I had a simular problem some years ago.
I remember that the monitor sometimes worked fine for
a few days, and then had that problem for a few days, etc.
Sometimes it came up, while switching on, but sometimes
halfway without doing anything particular. Anyway very strange.

I fixed it (together with a friend).
I still have the same gear now and it never happened since.

So here's what to do:

Check the PCB within monitor for broken 'routes'.
(Sorry I do not know what better word to use, I am not English).
You know the fix 'wires' on the PCB of copper (Cu).

I found two routes on the PCB broken. However it was very hard
to see. Use some kind of magnifier and good light.
And while you're busy, resolder all solder points, as many
were badly soldered (at least in my SM124).

I remember that one broken 'route' was so close to a solder point
that we hardly saw it.

Good luck.

1627. Blitz help needed.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-13 14:59:21 UTC
From: mather@sees.bangor.ac.uk
Message-ID: <24931.9103131501@helios.sees.bangor.ac.uk>
Source record: 48812

(This is a cross-posting to comp.sys.atari.st and comp.sys.atari.st.tech.
Please cc: or direct any replies to me at the e-mail address at the end
as I can post to but not read these groups. Thanks!)

Someone PLEASE help me!

I downloaded the blitz backup package from terminator/atari.archive
recently. Unfortunately, on printing out the wiring diagram I found
it to be almost unreadable. (Was it scanned in I wonder?) Can anyone
supply me with a better diagram (.gif preferred to .img), or a simple
ascii text file telling me how to make the cable?

Oh, and before I embark on this, can anyone tell me if it works for
definite on an Atari 520 STe (TOS 1.62)?

Again, someone PLEASE help me...

Cheers,

Paul.

e-mail: p.mather@sees.bangor.ac.uk

If your mailer can't reach me, I'm obviously not worth talking to.

1628. Programming hints ....

Newsgroup: comp.sys.atari.st.tech

Source record: 48818

Organization : Loughborough University, UK.
Keywords:

Because of memory limitation (I've only 1 MByte memory), I could not use GULAM shell for running TeX. I've also tried TeXshel2 (obtainable at atari.archive.umich.edu). But, the latter is really incomplete. As a result I decided to write my own shell -- my first GEM program. It is more or less based on TeXshel2 but completes things left in TeXshel2. However, I am facing some silly problems. Could be these are due to my inexperience in GEM programming. I would appreciate any help or suggestions in the right direction. BTW, I'm using Prospero Pascal (I'm not a C man) -- a compiler not famous for tight code generation and also I did not use any single AES routine and all function calls are through Propero's higher level interface.

Problem 1: I've provided options for file deletion and renaming. Once selected, the user is repeatedly asked for the file name (through fsel_input) followed by confirmation (for file deletion) or new file name (for file renaming) dialog until the user quits from the fsel_input level. This works more or less fine. But, the problem begins after a while, especially when the CANCEL button is selected more than once from the confirmation (for file deletion) or raname (for file renaming) dialog. The dialog boxes are left on the screen when this problem begins. I'm using standard form_alert (for confirmation on file deletion) and a simple dialog box (for file renaming) and use form_do,form_dial etc. for the latter. How, can I avoid these dialog boxes being left on the screen?

Problem 2: When the shell starts, the desktop colour is the usual gray (on mono monitor). After launching a program from the shell and when the control comes back to it the desktop turns all white for most programs. What is the easiest way to revert the desktop colour to gray?

Thanks in advance.

>In article <12052@hydra.Helsinki.FI>, luoto@cs.Helsinki.FI (Markku Luoto) says:
>>
>>I opened it once and the drive was a seagate... but how can you tell wether
>>it's a mfm or something else ???
>>
>
>Hello Markku!
>
>If the drive was a Seagate it is very easy: Look at the drive type on the cover
>If the last character was a digit, it was a MFM drive (e.g. ST 225, 20 MB
>5 1/4 inch MFM drive). If the last character was a R, it was an RLL drive
>(e.g. ST 238R, 5 1/4 inch 30 MB RLL drive).

From the Seagate Catalog, page 27:
none = ST412 MFM
A = AT bus
X = XT bus
N = SCSI or SCSI-2 (SCSI-2 is downward compatible with SCSI).
ND = Differential SCSI or SCSI-2
NM = Macintosh compatible SCSI
V = NetWare ready
R = ST412 RLL
E = ESDI
J = SMD-O/E or SMD-E (dual port)
K = IPI-2 (dual port or enhanced dual port)
S = synchronized spindle

Probably more junk than ST owners need to know. But now if you see one in a surplus store, you'll know what you're up against: for example, there's essentially no hope of connecting an SMD drive to an ST. ND won't work without some different kinds of bidirectional buffers -- the "plain" SCSI is "single ended"; differential SCSI lets you have 10 meters of cable, single ended SCSI lets you have 3 meters (according to the standard, but on my Mac IIci, it craps out with about 2 or 2.5 meters total cable). NM might also be trouble on a typical Supra/ICD/Berkeley ST interface.

1631. How does TOS know a disk has been changed (physically)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-13 21:05:07 UTC
From: rjwalsh@unix2.tcd.ie
Message-ID: <rjwalsh.668898307@unix2.tcd.ie>
Source record: 48825

How does TOS know that the disk in a particular drive has been changed?
i.e. when I do a 'dir' command in STOS, the disk whirrs. When I repeat the command, no disk access is performed. However, popping the disk out and in again, followed by a 'dir' causes the disk to be accessed.
Does the disk controller send an interrupt when the eject button for a particular drive is pressed?
Please email any replys. Thanks.

From: rosenkra@convex.com
Message-ID: <1991Mar14.083757.13185@convex.com>
Source record: 48820
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

thanx to the myriad folks you pointed out that GDOS font files are more
or less identical to in-memory or .fed font file formats, just with all
int/numerical data byte swapped (a la [braindead] intel - yuck :-).

i have written a trivial byte-swapper for converting these files, and if
i get a chance to clean it up, will post it. it should work in both
directions.

now, for those of u interested in nroff, read on. others can skip.

i have decided to upgrade nroff to be more a ditroff rather than an nroff.
this means support for lasers, filters, etc. it also seems the most
current *roff technology. however, i was sort of thinking of using
TeX fonts, to minimize the amount of font data on disk (for those with
TeX anyway). this is not quite portable, however. would u prefer unix
compatibility or common font data? hopefully i will still be able to
support nroff-style documents (fixed width fonts) via the propper
tab* and/or /usr/lib/fonts/dev*/* files (-Tcrt, for example). note that
i know that there are probably ditroff config files for TeX and/or DVI,
so this may be an alternative approach, too.

some people have already sent me their wish lists (thanx). now is the
time to enter yours. i am starting the rewrite now.

strickly speaking, it can't be a GEM-controlled menubar, but there is
nothing stopping you from writing your own, say under the AC window's
title/status bar, or even popup menus. these would work more or less
like dialogs. just watch out for getting sued if you are successful :-)

i have developed the special font for manpager which includes upper/lower
full greek set. i think they line up pretty much with ascii A-Z,a-z.
i will soon be posting a file converter for GEM to GDOS fonts and visa
versa. the only difference is that GDOS numerical data (ints and longs)
are byteswapped to intel order.

get the special font from manpager i posted a couple of months ago. it
will be a .FED file in the source post.

there may be others, too. mine are a pretty quick hack. there was also
a GDOS font editor uploaded to atari.archive (called gemfed.lzh, i think).

There is also a large arc file of GDOS fonts converted from the Mac, including a couple Greek and symbol fonts. I converted these using Neocept's Fontz! program. Unfortunately, Neocept doesn't really exist any more, so I don't know if you can still find this program for sale. (Ooops, I meant to also say "large arc file *on atari.archive.umich.edu*...)

Well dang, I just looked and it seems to have been moved to hyperspace.

1636. TT/Mega STE technical info wanted

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-14 13:03:15 UTC
From: hvaalde@cs.vu.nl
Message-ID: <9301@star.cs.vu.nl>
Source record: 48824

Hi,

Does any one of you has any information about:

- the format of the MEMCNTRL (0x424L) system variable in TT/Mega STE
atari seemed to have changed its meaning.

- how can one set and unset the use of the cache in TT/Mega STE.
(in a program)

- finding END adress of the ROM-space.

- the meaning of the system cookies set by TOS 1.6 and greater
(_CPU _FPU _VDO _SWI _MCH)

- the adresses of the control register of the 68882 FPU in TT
and Mega STE

Any information is appreciated thanks in advance

Harold van Aalderen (hvaalde@cs.vu.nl)

hvaalde@cs.vu.nl (Aalderen van Harold) writes:

>- how can one set and unset the use of the cache in TT/Mega STE.
> (in a program)

On the TT, you have to use the 68030's cache control register
to switch the processor cache on and off. The MegaSTE has an
external cache which is controlled by some other means; perhaps
they used some of the free bits in the soundchip's I/O ports.

>- finding END adress of the ROM-space.

I've been looking for a solution for this problem for quite a
while now. So far it seems that there is no legal way to find
out the end of OS code.

>- the meaning of the system cookies set by TOS 1.6 and greater
> (_CPU _FPU _VDO _SWI _MCH)
FPU: 1 for 68881, 2 for 68882
CPU: type of CPU (00, 10, 20, 30...)
VDO: type of video hardware (higher word: major revision,
lower word: minor revision)
SWI: state of internal DIP switches
MCH: kind of machine (Mega, STE, TT)

>- the adresses of the control register of the 68882 FPU in TT
> and Mega STE

In the TT, you must use the FPU instructions. In an MegaSTE,
the FPU registers should be mapped to the same locations as
they were with those FPU add-on cards for standard Megas.

Message-ID: <1991Mar15.043916.6702@ugle.unit.no>
Source record: 48828

Hi there.

I've just ftp'd the sources for gcc, and I'm trying to make a cross-compiler
for sun-3/60.
Cpp and cc1 seems to be working fine but:
The problem is:
A)
gcc.c seems to ignore the STANDARD_EXEC_PREFIX-definition, and
just tries to execute cpp, cc1 etc. not $(MYDIR)/gcc-cpp $(MYDIR)/gcc-cc1
etc, where mydir refers to the path I've exchanged with the "bammi"-path.
This is really no big problem, but...
B)
what about gcc-ld ? I guess I can't use the gcc-ld that was intended
for use on the sun (or can I) ?
I can't find any diffs/sources for this one.

I've applied the diffs for gcc-138, the patches for this diff, and the upgrade diffs
to gcc-139.
If somebody out there got this thing up and running, maybe you'd be so kind as to
send me a "cookbook" describing what you did, step by step.
(The docs I found on atari.archive seemed to explain
what to do pretty well, but since I can't get the thing running anyway...)

1639. Help setting up Opus

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-15 05:54:25 UTC
From: pdel@ADS.COM
Message-ID: <=QJ&WQ&@ads.com>
Source record: 48826

I'm trying to set up gdos for opus and am having problems.
I have gdos.prg and an assign.sys file, some screen fonts, and
a folder w/printer configuration files.

I don't know if I have the printer fonts, printer driver, and
a file called meta.sys. In the docs it says these are supposed
to be in the auto folder.

Can anyone help me get my boot disk setup for this program, and
point me where I can get the remaining files/prgs that I need.

thanks, Peter D.

Ok I need some advice/help from you guys.

My ST makes a rather horrid buzzing noise when I turn it on. The noise keeps on going for a few seconds when I turn it off. Nothing else happens (no boot-up from floopy, nothing on screen - dead). The noise seems to be coming from where the power lead plugs in to the ST.

Ok no prize for telling me the power supply unit is knackered, but if that is so can I fix it my self, and if so, how? I can't get it repaired on the guarantee as I think I voided that by adding 2MB RAM to the machine.

Thanks for any help.
Dave

From: adamd@rhi.hi.is
Message-ID: <2904@krafla.rhi.hi.is>
Source record: 48832
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Sometimes it is difficult to avoid having to run GEM programs. I would like to be able to junk GEM during a session without having to reboot, so that the memory can be used for something else. It is fairly easy to stop GEM and get on with something else in the underlying shell (just send KILL -17 to it), but my attempts to quit GEM result in a system crash shortly afterwards. Indeed the MiNT docs warn against killing GEM dead, but it should be possible if the right precautions are taken. What is necessary to do first so that GEM can be successfully removed without trashing the system?

Open for discussion.

Hi Everyone,

I've just been digging around on terminator, and found a program called vdifx110.lzh. I guess this is some sort of VDI fix, but alas, all the docs are in German. Can some kind soul tell me what bug this fixes, and if I need it. I've got TOS 1.6.

Thanks alot

Steve

1645. what TOS to use for STs with 68020 accelerator

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-15 12:37:59 UTC
From: wilko@idca.tds.PHILIPS.nl
Message-ID: <1234@idcapd.idca.tds.philips.nl>
Source record: 48830

I am investigating the use of a 68020 based accelerator card in a Mega ST. Currently, I use TOS1.4 Since the TOS as delivered by Atari is braindead enough to crash on anything else than a 68000, I wonder what replacement TOS people use when they use 68020 or 68030 accelerator boards. I also wonder what compatibility issues are involved. The accelerator I have in mind also has a 68000 on board to address problematic (with regards to != 68000 cpus) programs.

Any help appreciated

For one thing, Never ever use this thing, I have seen so many corrupted
PD, disk, that have come from People using it.
It does not use Index timing or any form of Verify for read or write,
and disk that have been copied can not be read on other ST's.
..!!.Even Hackers don't recomend it.!!

1649. Memory upgrade with 256Mbit rams.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-15 16:16:29 UTC
From: d88pt@efd.lth.se
Message-ID: <1991Mar15.161629.20972@lth.se>
Source record: 48835

HI,

I have been offered some 256Mbit rams really cheap. How do I fit them in
my atari 1040STFM. Can I just solder them on top of the existing rams?
What control signals should I use and where from on the pcb?
(I have 32 rams)

d88pt@efd.lth.se

1650. Re: My ST makes a buzzing sound

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-15 17:28:44 UTC
From: carter@cat27.cs.wisc.edu
Message-ID: <1991Mar15.172844.28890@daffy.cs.wisc.edu>
Source record: 48837

From: elliott@quando.quantum.de (C. David Elliott)

Ok I need some advice/help from you guys.

My ST makes a rather horrid buzzing noise when I turn it on. The noise keeps on going for a few seconds when I turn it off. Nothing else happens (no boot-up from floopy, nothing on screen - dead). The noise seems to be coming from where the power lead plugs in to the ST.

Ok no prize for telling me the power supply unit is knackered, but if that is so can I fix it my self, and if so, how? I can't get it repaired on the guarantee as I think I voided that by adding 2MB RAM to the machine.

Thanks for any help.
Dave

I would seriously consider getting a new power supply. I had the same problem that your having now, the cause is your memory upgrade is sucking more juice than your power supply can handle.

Try calling BEST electronics, and get a new power supply. That should do the trick.

Message-ID: <1991Mar16.023057.13422@odin.corp.sgi.com>
Source record: 48743

hi !!!

Damn, you have 256MBit RAMs cheap!! Man, did the Russians sell them to you? We can only manufacture them in volume in 1999.

Sorry for the nerd humor. You meant 256kBit RAMs. In any case, your 1040ST currently has all the RAMs it can handle. The ST architecture can handle up to two banks. A bank consists of 16 256kBit DRAMs or 16 1MBit DRAMs. Therefore, an ST memory can be 512 kBytes, 1 MByte, 2MBytes, 2.5 MBytes or 4 MBytes. That's it. RAMs with an access time less than 150 nSec will be of no additional value.

So dude, you're stuck. You need to use 1 MBit DRAMs either by purchasing a commercial upgrade board or removing the 256kBit babies and do some drilling to fit the 1MBit mamas into the same holes in the PCB. Please consult a qualified Atari technician.

A street price for one 256kBit DRAM at 120 nSec is $1.95 (up from $1.45 in early December). However, 120 nSec 256kBit DRAMs cost less than their 150 nSec counterparts. Later.

1654. Re: Memory upgrade with 256Mbit rams.

Message-ID: <EbsMM0y00VADECtKUj@andrew.cmu.edu>
Source record: 48744

First, if you have access to 256 Mbit parts cheap, I'd like to pick up a few! I'll assume you mean 256 Kbit. The ST's MMU expects to see one or two banks of RAM, where each bank is 16 bits wide. So, you need to have 16 chips to fill a bank. The 520 has one bank of 256 Kbit chips, the 1040 has 2 banks of 256 Kbit chips. The Mega 2 has one bank of 1 Mbit chips, and the Mega 4 has two banks of 1 Mbit chips. The final answer is that, since you have a 1040, your machine already has both banks full of 256 Kbit chips, so you can't easily upgrade with 256 Kbit parts. You must use 1 Mbit parts to replace one or both banks, getting 2.5 Megs or 4 Megs respectively. While it is theoretically possible to do what you are attempting, it likely would wind up being more hassle than it's worth (even if you got the chips for free). Buy 1 Mbit parts to upgrade your existing machine, or better yet, an STE, and upgrade with SIMMs.

Sorry, this probably isn't the answer you wanted to hear.

1655. MY VME SLOT

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-16 04:07:04 UTC
From: carter@cat27.cs.wisc.edu
Message-ID: <1991Mar16.040704.1442@daffy.cs.wisc.edu>
Source record: 48748

I just got done looking at the size of my VME slot in my MEGA STE and it seems like given the size of the card, you could put some pretty awesome hardware on it with all that room.

Anyone have experience designing VME cards? I wonder if Mr. Small would consider an SST board as an add on card, instead of ripping my poor machine apart.

I will be getting complete developer documentation in a few days so I should know the whole story very soon.

What is really interesting is that the serial port is not even a real serial port, per se..it comes straight off the mother board. When and if a card ever comes out, this port will have to be removed as all it is, is a metal plate with an RS422 male connector ribbon tied to the motherboard.

I have read about a lot of graphics cards for VME based computers. I wonder if it would be possible to design graphics cards for the MEGA STE???

And in addition to these fine works of software, there is a DA paint program that, when it's DA slot is selected from the menu, replaces the desk menu with it's own thus allowing a menu selection. Once this is done, the next time you drop the desk menu on down, it is back to normal.

1657. Help with Lattice C v.5

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-16 22:14:24 UTC
From: heavy@zip.eecs.umich.edu
Message-ID: <1991Mar16.221424.10337@zip.eecs.umich.edu>
Source record: 48746

Can anyone with Lattice C v.5 tell me why this won't
compile and link:

```
#include <stdio.h>

void main(void)
{
char str[50];
int num;

num = 10;

sprintf(str,"%10d",num);

printf("%s\n",str);
scanf("%s",str);
}
```

My compiler options are:

```
-b1 -d0 -fl -fm -m0 -mt -r1 -rs -t
```

Any help would be appreciated.

Message-ID: <IbshhLu00VADIIZ2Ev@andrew.cmu.edu>
Source record: 48745
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I just recently got my 4 Mb system, and I just tried gcc-ar for the
first time. It doesn't seem to work. With everything in the right
place, the following occurs:

```
% ar r libab.olb abcd.o
Creating archive file `libab.olb'
ar: access denied for libab.ol$
cmd exit code 1
%
```

... and a very small file named libab.olb is created. A file named
libab.ol$ which is a few bytes larger than abcd.o is also created.

The version of gcc-ar I am using is the one that's in the bin.zoo
from terminator (gcc-1.37).

Any help is appreciated.

I'm running gcc from RAMdisk on my 4 Mb system, and am playing a balancing game between disk space and memory. I have been getting an error from GCC, namely "Virtual memory exhausted." Does this really mean "disk space exhausted," as it seems to imply, or does it mean "not enough memory?" It doesn't seem to matter which version of gcc I use, be it 1.37 or 1.39.

Thanks in advance,

-Eric Stuyvesant

1660. New uploads to atari.archive

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-17 21:00:08 UTC
From: boyd@nu.cs.fsu.edu
Message-ID: <1991Mar17.160009.28770@mailer.cc.fsu.edu>
Source record: 48750
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Here are some new uploads to atari.archive (141.211.164.8):

size name

24320 areacode.lzh Find city and timezone from phone areacode. Very
handy for decoding your phone bill!

15872 bigcolor.lzh big monitor emulator that works in color.

38391 cal47.arc An excellent calendar program. Allows you to install
a "reminder" program in your auto folder to warn you
of upcoming events (I will never forget my girlfriend's
birthday again!). Very well done, this is a must have.
This version is only a few hours old!!

16896 djenvelp.arc Prints envelopes on Deskjet printers

16923 dskchart.arc Gives a graphical representation of free disk space on
drives. Can also give more detailed info.

28544 edhak_19.lzh This is a combination diary/text editor/memory editor/
disk editor. I think it is an acc.

37760 edhakdoc.lzh Fuller docs for the above program.

23808 fcopy30.lzh A german PD copy/formatter program. Very nice.

108672 nagel.lzh A bunch of Nagel spectrum pics. Very well done.

16512 postal20.arc A database of postal abreviations for US and Canada.

5756 specshow.arc A spectrum pic viewer. Also allows you to compress
the pictures, and view the compressed ones.

36864 stunzip.arc An ST version of the ZIP archiver.

116352 subcl114.arc A PD version of El_Cal, a very user friendly and
powerful mathmatical calculation program. A must
have!

54272 tcos.arc A stripped down clone of Hypercard. Kinda interesting.

Please note that I had nothing to do with any of these programs except for
Cal47, for which I merely made some suggestions to the author. I really
recommend this program, it is actually USABLE (as opposed to all the other
time management type programs I have used for the ST). Sub_Cal is another

gem in this group. I used a previous version heavily in several of my undergraduate calculus, statistics, and discrete math courses. Enjoy!!

Oh, on a couple of these guys I added a small doc file (if there was not one included with the arc). Just a one or two liner.

It means "Real memory exhausted" on the ST, since we don't have any virtual memory. (Although if you have a TT, and write the necessary software, this could change...)

I find gcc usually wants 2 megabytes; if your functions tend to be large and complicated, 2.5 megabytes may be necessary.

libab.ol$ is, actually, what you are looking for. I had the same problem
with gcc-ar until I recompiled it with Eric Smith's MiNT library (the
panacea for program woes). Just rename libab.ol$ to libab.olb and you'll
have your archive.

It might also mean that you are hitting the 40(+) folder limit. Try
increasing the number of folders available with folrxx.prg (or you
hard-disk driver) and see if the problem disappears.

ST PAD

The ST Pad is a notepad version of the Atari STe computer. It is
fully ST compatible, and will run any software which is written
to work in the 640 x 400 monochrome mode.

The ST Pad weighs 3 pounds and has an A4 size footprint. There is
no keyboard, mouse or floppy drive. The entire user interface is
based around a pen device. With the pen you can draw on the touch
sesitive LCD as if it were a piece of paper. The ST Pad will
recognise your handwriting and written gestures removing the need
for a either a keyboard or mouse.

Instead of a mechanical floppy drive the machine uses two silicon
drive slots for removable media. The slots can take RAM or ROM
cards for data storage or application software. Each slot can
accomodate up to four MB of data.

The hardware is designed to radically reduce power consumption. This
has been achieved with some innovative design techniques resulting
in a battery life of over ten hours.

One of the most important new features is a suspend and resume mode.
This allows the user to put the ST Pad into a standby mode and then
resume work later at exactly where he or she left off. In standby
mode the the batteries can last several months without losing data.

CPU: 68000 at 8MHz
RAM: 1MB and 4MB versions
ROM: 512KB
Other: PSG Sound
Real time clock
low power control circuitry
Pseudo static ram
External FDD (optional)
Size: A4 Footprint, 36mm thick
LCD: 640 x 400 STN, no backlighting at the moment.
Stylus: Wired stylus with two buttons L/R Mouse functions)

Connectors:

MIDI 2 x 5 Minipin
RS232 1 x 9 pin
Parallel DB25
Power 3 pin

DMA 28 pin Micro-D
Keyboard RJ11, compatible with the Mega ST
JEIDA cards 2 slots, 68 pin
Stylus 4 pin MiniDIN
Expansion: 120 pin connector, WREN expansion compatible.

External expansion:

Address bus, Data bus, interrupts, compatible with WREN, supports
WREN compatible locking screws on the side of the unit as well as
underneath.

Software:
TOS with additional stylus features including mouse emulation and
handwriting recognition.

>and disk that have been copied can not be read on other ST's.
>..!!.Even Hackers don't recomend it.!!

Roger is absolutely right in saying that BLITZ should not be used for disks that are bound for distribution. While it is fast, hence the appeal to small-time mass producers, it does not do anything about reliability or transport-ability; however, this is not BLITZ's fault! It's not designed for this purpose. Anyone who uses BLITZ to produce disks that people pay money for (even the "handling" fee for PD software) is asking for trouble.

BLITZ is intended to be a method for owners of copy-protected software to make legitimate backups of their disks. I would try software-only backup programs like ProCopy first; however, sometimes BLITZ will work where ProCopy fears to tread. And BLITZ is basically free (just some cable, some connectors, and some time.) Not a bad deal.

Transportability should not be a problem for the legitimate user unless he has two or more machines that he may want to run the software on. No more than one at a time, of course.

Another, commercial, alternative is the synchro-express cable. It appears to be the same set-up as BLITZ, except that there is a chip of unexplained purpose inside the parallel connector. I have a paranoid fantasy that this chip serves no real purpose at all (like a signal buffer) except to lure the unsuspecting customer into spending ~$60 on something he could get for free.

Has anyone had any experience with synchro-express, especially how it compares to BLITZ? Please share.

1672. Re: what TOS to use for STs with 68020 accelerator

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-19 01:40:26 UTC
From: mc4c+@andrew.cmu.edu
Message-ID: <QbtKk_G00VID01G4Va@andrew.cmu.edu>
Source record: 48756

I believe you gotta use 1.6 or above, as these were the first ones where Atari started to get there act together, and realized what year it was, etc. That is why GBS licensed it for the SST. By the way, Why couldn't he make a board specifically for the MEGA STe that doesn't have TOS, so people can save money by unplugging the ROMs that some with the machine?

1673. Re: Setting Floppy Seek Rate in all TOS versions

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-19 04:44:54 UTC
From: vsnyder@jato.jpl.nasa.gov
Message-ID: <1991Mar19.044454.24718@jato.jpl.nasa.gov>
Source record: 48758
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Here's the poop on setting the seek step rate for floppies, from page 60
of the Rainbow TOS distribution:

"Floprate: - Floprate, XBIOS function 41, checks or sets the seek
rate for a floppy drive. This is new; the seek rate
must be set with (previously) undocumented variables
on earlier versions of TOS.

Floprate example.

```
int devno, newrate;
oldrate = Floprate(devno,newrate);
```

This returns the current seek rate if newrate is -1,
otherwise sets the seek rate to newrate. For doing this
with previous versions of TOS, the seekrate byte
locations for drive A and B are:

OS Version	Drive A	Drive B
0x0100	$A09	$A0D
0x0102	$A4F	$A53

In either case valid seek rate byte values are:

Value	Rate
00	6 ms
01	12 ms
02	2 ms
03	3 ms

This call does not range check the drive ID or new seek
rate. If devno is zero, it assumes drive A:, if
nonzero, drive B:." That's 41 decimal.
You can get the TOS version from offset 02.w from the place pointed at
by 0x4F2.L (_sysbase).

DRI format is Alcyon format, which is the same as Sozobon C, for
which full C source code is available (compiler, assembler, linker,
libraries, utilities).

I don't know about GST.

From: ekrimen@ecst.csuchico.edu
Message-ID: <1991Mar19.080947.6091@ecst.csuchico.edu>
Source record: 48763

I was just checking out comp.sys.next and someone mentioned 1.44meg SCSI floppy drives for $299, then 2.88meg drives. I assume these are 1.44meg drives with SCSI controllers attached. Anyone know if these could be connected to an ICD host adapter (with a hard drive already attached)? Yes, $299 seems kinda expensive, but Dream Park's 1.44meg external drive mod, including drive, lists for $350!

1678. GCR / MegaST problem?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-19 15:34:07 UTC
From: SNYDERS@process.com
Message-ID: <28122@dime.cs.umass.edu>
Source record: 48764

I just purchased a used spectre GCR. When I started using it in mac mode it would crash. I looked in the documentation and it says that some Mega2s had some marginal chips in them and the solution was to replace them.

I checked my machine and sure enough I have the bad chips (SGS 74LS373).

I am thinking of doing the work myself and would like to hear from anyone who has had this problem and can offer any advice such as.

- Replacement chips used. I would hate to put in new chips that have the same problem.

- Tips on soldering. My main concern is heat damage to other chips and the new chips. I have done soldering before but not on a pc board.

- How difficult is the job. Is there any thing else I should know.

Thanks,

John Snyders email: snyders@process.com

1679. XLISP and arrays

*****************************************************************************

I have 3 1040STE's made by ATARI corporation. These machines are brand new
and were obtained through liquidation at a going out of business sale in
Minnesota.

Machines Features:

- 8MHz 68000
- 3 8bit digital-analog sound converters for PCM Stereo Sound output
(Standard RCA Jack hookup for stereo amplifier)
- 720K Floppy Drive (3 1/2)
- Memory; 1Mb standard. Expandable via Industry Standard SIMMS to 4mb
- Video; 4096 Color palette; with 3 different video modes:
1) 640x400 Monchrome mode
2) 640x200 4 Color mode
3) 320x200 16 color mode
- Can use either a TV or a RGB monitor for display. Compatible with
Multisync monitors with special cable.
- MIDI(Muscial Instrument Digital Interface) ready ports.
- 95-key keyboard
- RS232C, Centronics, DMA Hard Disk, cartridge ports

Price $399 includes: 1 Box of 3 1/2 inch disks
Shipping anywhere in USA.
1 Disk of PD software

Really nice machine. If you want more info, please call me at 608-264-3622
or during the week of 23-April 2nd: 414-494-4114

INTERNET a great place to save money.

> It can't hurt!

> Marshall

Thanks, but that problem is unlikely, if possible 8-). In any case, the
mouse and keyboard problems have now appeared in regular ST mode. I
got a new Ikbd processor from Best Electronics, but that hasn't
helped. A reset *always* fixes things for a while, so I rather doubt
that the keyboard connection is intermittent, it's hard to check!
I am now gearing up to figure out which 6850 ACIA to remove and
replace (I *did* get one from Best 8-). If I foul things up, it's a
new STE for me 8-(). At least my trial run for desoldering, replacing
the connector in my mouse, went well. I recommend the Radio Schnook
desoldering iron 8-).
A couple of interesting things came from my talks to the Best
Electronics guy. One is that the Mega keyboard is almost a drop in
fit for the original (external PS and floppies) 520ST, (same large
connector) and is only a little more expensive to buy ($110 vs $90
8-). The other interesting thing is that there are two versions of
the keyboard processor. I have an '85 ST, but luckily it used the
later processor -002. If yours is a -001 version, you need a whole new
keyboard if it goes bad (I _hope_ that version was only on the
developer 520s, this is, after all, ancient history 8-).

By the way, sorry if I have seemed unresponsive, but we lost our news
feed here for most of last week 8-(.

Yup, no DA can touch the menu bar. However,try and get in touch with Eric Rosenquist (SP?????) here or elsewhere. His program, STeno does what you want *very nicely* with a separate menu bar inside the window (menus even "drop up" from the bottom if they can't drop down properly). Perhaps he could give you some pointers, or maybe even release his code - when it's no longer a major selling point of his programs 8-). I'd love to be able to do that - even with regular programs.

1687. Did Atari screw up AGAIN?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-19 20:12:18 UTC
From: carter@cat27.cs.wisc.edu
Message-ID: <1991Mar19.201218.15050@daffy.cs.wisc.edu>
Source record: 48774

Maybe I am just a naive dunce, but I thought I would have the option of
putting in my MEGA STE a nice cpu card someday, or even a nice graphics
card...So what?

Well, I gave the specifications of Atari's VME bus to a freind of mine to
see exactly what I could do and couldn't do and he comes up with the
following very depressing comments.
^^^^^^^^^^

The fact that the slot is 3U is depressing, the bulk of the VME market is
in the 6U cards, so your options are going to be very limited. Looks to me
more like a way for atari to use a standard bus and allow some kind of
expansion. So you have one 96pin euro connector and about a 4 inch wide slot?

If you really wanted to use 6U cards, you could use the connector with some
kind of cable/extender arrangement to an external case which could
have perhaps multiple card slots. The statement that it is slave only pretty
much rules out CPU cards in the usual sense. Lack of bus arbitration means
you cannot use slave cards (like disk controllers) that want to do DMA
transfers.

This bus would be ideal for things like D/A and A/D converter cards.
PIO cards, communications cards (so long as they avoid DMA - ethernet notable
here). Graphics cards would be a possibility.

The power you quote is very limited (only 50MA of +-12 !! the 2A of +5 would
be just enough to power the single 3U card). If you set things up to an
external multislot box, you would definitely want an external and INDEPENDENT
power supply (and perhaps buffering for the signal lines -- but this would
introduce delays and skew ....).

Take all I say with a grain of salt. VITA (VMEbus intl trade assn or something
like that) publishes a yearly directory of VME products -- I used to have one
of these. Some other VME books are out as well.

Maybe this is just one guys opinion. Maybe he is wrong?

I think I am going to cry....it won't be the last time either I have a feeling.

1689. FTP problems

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-20 03:54:08 UTC
From: archbold@bluemoon.uucp
Message-ID: <X103y1w163w@bluemoon.uucp>
Source record: 48782

Hi Netters!

Recently I've had some problems with the FTP stuff, and I want to share them with you, to check if anybody had similar problems. Perhaps w we can find a solution to mine.

I have an account on a VAX at OSU where I do most of my school related computer work on a VAXstation. Of course that VAX allows me to use FTP. The problem with using it is that it writes on High Density disks which my 1040ST doesn't know how to read. Fortunately at OSU there are many FTP sites, and one of them has an IBM that can write on 3.5" high and double density disks. That's where I would usually go to do my FTP'ing. Nowadays when I try to reach atari.archive the program tells me that sites can be reached only from recognized machines (whatever that means). Although the machine won't let me connect to atari.archive, it WILL let me connect with my local VAX. So, I started d/l stuff from atari .archive using my VAX and then d/l stuff from the VAX to my disks via the IBM machine.

It's all nice and sweet, except that none of the programs and pictures I d/led work on my ST! To do transfers I used the IMAGE type (in both to and from VAX), so everything should be OK...

This thing gets even wierder: today, after all the downloading and running back and forth between buildings during finals week, I brought a disk full of spectrum pics and dskfonts.arc. Tried to display the spc pictures from desktop (I have a spectrum viewing program installed as desktop application), and only two of the pictures would work. Then after viewing them once, they wouldn't load! The program would abort saying the format is wrong! BUT THEY LOADED ONCE, and I'VE SEEN THEM WITH MY VERY EYEZ!!!

This makes me believe the problem might lie somewhere in that IBMs format, but that doesn't seem probable...

So, what do you think? Either mail me, or post if you think it would enhance discussion on the net...

1690. Forcing the scan rate to 50Hz [Sure wish they wouldn't!]

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-20 05:26:58 UTC
From: dmb@wam.umd.edu

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

>European TVs work at 50 Hz. We make up for the fewer frames per second by
>having more vertical resolution and properly-encoded colours.

The only real reason game writers alter the scan rate is so the game play timing won't change. Games run 16.3% faster on U.S. ST's because the scan rate is 60Hz here. This means Joust, e.g., is more difficult in the U.S. than it is in the UK, something I always make clear when comparing high scores with my British competitors. :-)

An example of a problem caused by the scan rate difference is the treasure room in Guantlet II. U.S. players will notice that the timer only counts down to about 4 or so, then the level ends. This is because the countdown code stupidly relies on the scan rate being only 50 frames per second (it counts a second by waiting for 50 vblanks to elapse). On U.S. machines 50 vblanks occur in 5/6ths of a second, so the timer counts down too quickly, and you only get 16.6 seconds in the treasure room instead of the normal 20. (Or is it 25?)

To avoid the timing problems, some European programmers force U.S. machines into 50Hz mode. (This is accomplished by twiddling a bit in one of the video hardware registers.) Unfortunately, many early ST monitors (those made by GoldStar, I think) just can't handle the switch, and the monitor goes completely off sync. (We're talking "instant headache mode".) It's a shame too, because the GoldStars had better picture quality to my eyes. Many European games and demos are completely unuseable on my machine -- I can only assume that European folks just don't know their stuff doesn't work on a substantial portion of U.S. machines. Thank God Speedball II doesn't change the scan rate...

(Hmm, this sounded a bit technical. Followups to c.s.a.s.tech...)

>later processor -002. If yours is a -001 version, you need a whole new
>keyboard if it goes bad (I _hope_ that version was only on the
>developer 520s, this is, after all, ancient history 8-).

It's not only in developers' ST's. A friend of mine is blessed with one,
and boy is it screwed up. The mouse pointer will suddenly start moving
on its own every once in a while, and the keyboard processor randomly
"presses keys" whenever the joystick is being used. This problem is
in enough ST's that Michtron's Time Bandit requires you to press 'Q'
twice to quit the program. (I suppose they could have done that for
other reasons, but I'm suspicious...)

Add to this the charming behavior of early ST MIDI ports (1986 and
earlier) -- they drop bytes every once and a while. Just great for
testing a multiplayer game that syncs up over MIDI!

Hi... I have one quick question... I have an old Sh204 Atari Hard Drive 20M
Is it possible to buy either a 3.5 " hh Maxtor 95 MB SCSI drive or a Rodime
5180 -S 5 1/4 " SCSI drive (133 MB) and use it with my existing sh204's
controller card? Or can I trash the tandon HD inside and just connect one
of the drives mentioned??? Or will I have to buy a new card/case etc???
Thanx
Jeremy

1693. memory upgrade woes on a Mega 1

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-20 11:06:58 UTC
From: wilko@idca.tds.PHILIPS.nl
Message-ID: <1236@idcapd.idca.tds.philips.nl>
Source record: 48770
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I am experiencing some problems in upgrading a Mega 1 to a Mega 2.5. I did replace bank 1 consisting of 4 x 414256 (256Kx4 chips) by 16 x 411000 (1Mx1). The missing A9 line (not used on the 414256) is connected to the 411000 via a series R of 33 ohm.

Result of all this: the ST recognizes the new bank 1 as a 128k bank, giving me a total of 640 kbytes. In addition a very interesting moving pattern of vertical bars appears on the screen. The bars are approximately 8 pixels wide. I get the impression that this screen pattern is due to non-refreshed dram locations. Apparantly the ST thinks (?) that 64 k drams are used for bank 1, resulting in a refresh cycle on 8 address lines (256 address refresh cycle) instead of the 9 address and 512 refresh cycle a 1Mbit memory cell requires.

My question: does Atari use a different MMU chip in the Mega 1 with 414256 chips which cannot handle the 1Mbit cells? This would mean I am stuck with 1Mbyte. I'd love to see Spectre running with some more memory and Multifinder.

Any help appreciated

It means that gcc hasn't enough memory to work. He says virtual memory, because gcc was first designed for UNIX, where you have virtual memory because of paging and/or swaping.

Synchro Express, well I brought mine from the USA, it has 2 modes
for copying, Express and Synchro.
For some reason or other it will only copy 2 sided disks in Express mode.
not in Synchro mode, also very slow to copy disks in Synchro mode.
Note, will not copy disks that use under index hole data, and a few other
newer disk that have come my way.
Have noted that they advertise Version II, now in the UK. I don't know
what version my one is, but the Program is Version 2.1
Note, it still does not verify in Reads or Writes and you need 2 drives..

Hello,

I recently downloaded the 8bit emulator from Umich atari.archive
and was very impressed. Having been a faithful Atarian since the mid-80's
I really want to utilize this program. It mentions an ST Xformer cable, and
something about a 5.25 drive. Does anyone have the full setup and if so
is this with the IB drive or an actual 8-bit drive? Can this emulator run
all disk based software? Specifically, can the emulator use printer and
modem ports just as though they were 8 bit ports? Please E-mail any
and all info you have on this, I'm not sure I want to get the full package
if it can't do everything the old 8-bits could.

Thanks,
Technoid

From Mtools 2.03, patch #3:

# Mtools was posted to the unix-pc.sources news group (and mailed to the
# moderator of comp.sources.unix) on the 17th of September 1990. Since
# then, patch #1 and #2 have been posted to unix-pc.sources,
# comp.sources.bugs, and emailed to Rich Salz.
#
# In addition, the current version of Mtools and all the patches are
# available via anonymous ftp from cerl.cecer.army.mil (129.229.1.101).
#
# Emmet P. Gray US Army, HQ III Corps & Fort Hood
# ...!uunet!uiucuxc!fthood!egray Attn: AFZF-DE-ENV
# fthood!egray@uxc.cso.uiuc.edu Directorate of Engineering & Housing
# Environmental Management Office
# Fort Hood, TX 76544-5057

Just a few days ago, I modified Mtools so that they can read
and (be careful!) write single sided 3.5" floppies and e.g.
floppies with 10 sec/track:

Hmm, if you already have it on a DSDD disk, why not just transfer it on a PC to a DSSD disk (by formatting using "format x: /t:40 /n:9"). If you still want mtools, you should ftp it from 129.217.64.63. All I had to do to compile it was to add a "#define sparc" somewhere, the docs tell it all. Email if you have questions.

I used to have only a mono monitor and would use an old color color TV
with it. The TV's controls were broken so I couldn't adjust the picture
for 50Hz games and demos... Fortunately, I now also have an SC1224 that
syncs to 50Hz properly.

What I used to do, though, is if the game wasn't too heavily copy
protected, disassemble it and look for code which changes the hardware
register that controls the sync rate, then change it to put it in 60Hz.
Most of the time it worked. I forget the exact address of the register
but if anyone's interested I can look it up.

After a while, I wrote a TSR that could toggle between 50Hz/60Hz using
a hot key. This was more hit and miss, since most games/demos autoboot
making it hard to install the TSR and also some completely take over the
keyboard so the hot key doesn't work.

If the Hz change worked, it almost never affected the functionality of
the game.

|> this?

If you have the mtools suite on the Sparc, it's simply a matter of putting the DS ST disk in the slot, and using mdir (directory listing) and mcopy to transfer the data. To transfer text files, use a -t flag on mcopy to translate the Atari CRLFs. Binary (.PRG, .RSC, etc...) don't need this flag.

Examples: copy from disk to Sparc: mcopy a:/tetris.prg tetris.prg
mcopy -t a:/tetris.doc tetris.doc
copy from Sparc to disk: mcopy tetris.prg a:/tetris.prg
mcopy -t tetris.doc a:/tetris.doc

I use this often and have no problems whatsoever. I format my disks on the ST, and it sure beats the hell out of playing with kermit on an attached PS/2!

Non-SGS 74LS... OR: For improved handling 74HCT373 or even better 74ACT373.
They are 100% compatible, but much more faster and reliable. They are
essential if you are planning to install an accelerator later...

I changed my 1040 to Mega4 and first thing was: 74LS's out and 74ACT back...

>- Tips on soldering. My main concern is heat damage to other chips and the new
>chips. I have done soldering before but not on a pc board.

Small enough tip and keep it well cleaned! Not too hot. Loose the old chips
one pin at a time, warm the pin and pull it up with a small screwdriver.
If you have IC desoldering tip, use that. Vacuum tin-removers are not reliable
for taking ICs off from a pc board... The holes are so small.

>- How difficult is the job. Is there any thing else I should know.

Not very, but takes a little time... Don't burn your fingers!

1709. Problems with second drive

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-21 14:55:39 UTC
From: swood@vela.acs.oakland.edu
Message-ID: <5489@vela.acs.oakland.edu>
Source record: 48785

About a year back, I bought a used atari 520 STfm with 1 Meg memory, that has a non-standard internal drive. I recently got a ss/dd drive to hook up to the B drive port, and all hell broke loose. Though I have managed to have limited problems with the internal ds/dd, they have been limited. I hope to go inside and clean the connections, but in the meantime, if anyone knows of any reasons why the addition of the extra drive might cause my machine to have distorted data read/write and to give "drive not responding" errors, please let me know. (even when I disconnect the b: and reboot, the internal still gets some errors.)

When the b: drive is connected, the a drive tends to read alright with an occasional "... not responding" error, however, when I format the a: drive to 2 sides, disconnect the b: and reboot, the system will not even bring up the full desktop (no icons at all)

thanks in advance

Source record: 48856

Hello:

I was currently in the market to buy an Atari 1040st, at an EXTREMELY good price. But lo-an-behold, the system did not come with a monitor.

"No Problem!" I thought... "I'll just hook it up to my TV Set like my friend did his 520, and I did with my 8-bit!!" I thought I had the problem licked... WRONG!!!!

Little did I know, but the 1040st was not built for my type of person in mind. The 1040st does not have an RF modulator that would allow me to hook the machine to the TV Set!!!

If anyone has any possible solution, PLEASE reply!!

Later!

Well, yeah, I guess I do. In case you're wondering, the technology _does_ exist. I think Xerox PARC has stuff like this going. I friend of mine works at Xerox over here etc...

>Thanks for posting the information. May I ask where you found it? I
>just like to know the sources of these things. :^)

The CeBIT article came from a local BBS. The specs on the ST Pad and ST Book came from Atari's BBS here in Markham. They even set up a special area for these computers on the BBS already.

This means a malloc() call, or possibly an alloca() call, failed. Either
__stksiz is set wrong (should be -1 for GCC 1.39) or your memory is
fragmented or your RAMdisk is too big. Or something.

Yikes! Do I really have to go into the dangers of this kind of thinking?
NEVER use direct DMA access. You are SURE to get it wrong and screw up
something. Who has drivers which DON'T support the raw-device bit?
Whoever they are, their drivers are not complete, at least as defined by
Atari's documentation of the Rwabs() call.

Hmmm... we should really put this in a FAQ list somewhere...

> If you have the mtools suite on the Sparc, it's simply a matter of putting the
> DS ST disk in the slot.

Also, if you (the original poster) have problems with it try recompiling
mtools with DUP_FAT #define'd. This causes both FAT copies on an ST Disk
to be updated. Since you're reading I don't think it should make any
difference... but if you want to write to it, mtools won't write an ST
compatible disk with DUP_FAT.

1718. gnu emacs and TERM

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-22 11:43:37 UTC
From: lynbech@daimi.aau.dk
Message-ID: <1991Mar22.114337.16627@daimi.aau.dk>
Source record: 48847

In order to get the function-keys to work on my atari under emacs, I have been experimenting with setting up a vt52.el file so that keypad.el would run. This may not be the easiest solution, but it is standard to the way emacs handles terminal specific things.

I managed to get the file together, but I can't emacs to load it automatically. The problem appear to be that (getenv "TERM") always returns "vt52-emulator", REGARDLESS of the real value of TERM. I have tried this, both with environ.prg and under gulam, but no matter what TERM is set to, (getenv "TERM") still returns "vt52-emulator". All the other environment variables works fine however.

Why is this? My suspicion is that it has something to do with a termcap hack. My version (which I think comes from atari.archive, at least the st hacks bears Bammi's name) doesn't need the termcap, so perhaps something has been hardcoded into my emacs.

1720. ICD Drives and Video Corruption (and Spectre 3.0)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-22 16:05:08 UTC
From: rcd@cbnewsj.att.com
Message-ID: <1991Mar22.160508.18076@cbnewsj.att.com>
Source record: 48853
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

This falls into the hard-to-believe category: accessing your ICD hard drive can mess up your screen image. Certain DMA accesses or electrical noise to the ICD host adaptor will freak out the video refresh logic.

Spectre 3.0 shows up this problem. Right after the "Welcome to Macintosh", my mono monitor screen became a blurry fuzz of quivering horizontal lines and distorted shapes. Says I, "Huh?" Had never seen this before, certainly not with Spectre 2.65.

Left a plea for help on GEnie's Gadgets RT, but even Dave Small was puzzled. Then came some news from a couple of other people who had the same problem: it's the ICD host adaptor, they said.

To solve the problem, they said, get a 22 pF capacitor, and solder it between pins 12 and 13 of the DMA IN connector on the host adaptor board.

I called up ICD, and they said, yes, it's a known problem, and yes, the solution is as described above.

Hope this helps someone,

Rana Dutt

Message-ID: <9103222256.AA06374@uk.ac.oxford.ecs.booth16.ecs>
Source record: 48858

Hi there, does anybody have any idea what might be involved in trying to get a mono monitor to think it's a colour monitor (ie, to display low and med-res screens in greyscale) in *hardware* ?

As far as I can tell with the RGB outputs, it would probably be a question of simply hooking up a resistor net with the right `weightings' to generate a mono intensity signal. [At a guess, although I haven't put a scope on them, I imagine that the RGB and Mono lines are simple intensity signals with no additional sync information at all].

The major problem as far as I can tell would be the sync signals. What would happen if I tried driving an SM124 with a 50 Hz frame frequency (or 60 Hz, if neccesary)? I guess that I'll either get no picture at all, or get something like a two-thirds height picture.

Thanks,
Ray.

p.s. I modified my picture size last week after reading reports about people doing this on comp.sys.atari.st.tech, reckon I've got another 20% of useful screen area now...

1722. connecting VGA mono monitor to ST

> must be set with (previously) undocumented variables
> on earlier versions of TOS.

This is true if You want to set different seek rates for both drives.
If You want to set both drives to te same seek rate, place the new seek
rate in adress 0x440 (zero: six, 1: 12, 2: 2, 3: 3 milliseconds) and
call the function pointed to by the vector in adress 0x46A (hdv_init).
This will make new Bios parameter blocks for both drives and tel TOS to
use the new seek rate.
Works on all TOS versions, cause it uses only documented system
variables.

SIPPs are SIMMs with pins. They use single in line sockets very much
like IC sockes.
I did desolder the pins and clean the contacts of some SIPs to make them
SIMMs again. They work fine.

9 bit SIMMs are no problem in either MacSE/SE30 or Atari STE. Tried it
out.
The 9 bit SIMMs/SIPs contain one more chip, but the inout-pin of this
chip is not connected to anything in the STE. To be sure, connect the
Data 9 inout to a 10 k pullup to 5 volts. This will make the chip read
in a 1 on every write and stop it from doing wild things.

1726. Using curses and termcap

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-23 17:45:30 UTC
From: pietrzak@skybridge.SCL.CWRU.Edu
Message-ID: <1991Mar23.174530.23356@usenet.ins.cwru.edu>
Source record: 48864

I've recently been attempting to move a program which uses curses to my atari. I set up the GCC package from atari.archive, and (amazingly) everything went smoothly from there. The only problem I've encountered so far is apparently with getting curses to read from the termcap information. I've tried setting a TERMCAP environment variable, putting the termcap file in a /etc folder, putting it in the current directory, etc., but I still can't seem to get it (my tabs aren't working properly). Anyone know what I'm doing wrong?

(I'm using the termcap file found with the curses distribution, and setting a variable TERM=atari. Also, I'm running under msh of Mark Williams C fame.)

Thanks

> Marshall Lake@irscscm.UU (310)

> Simply incredible!!

Not really. Look at recen PC Worlds, and lookit whats goin on over i the MesS-DOS, Windows world. PEN Windows, and the new GO systems, pen pad. They will have opersting sytems BASED around this technology form the ground up, with pseudo 3D GUI and a lot of other niceties. I doubt Atari will really go the whole 9 yards with this. They have just jaded me too often in the past. I have STacy, so I know what Atari doesn't do right :^(!
As far as VME video for the MEGA and TT. Yes you can have VME video, but so what. with no attempt by atari to form any reasonable enhanced video support ala 32bitQuickDraw, all intensive graphics software will have to go through loops (PC type drivers etc.) to run on more than a few boards.

1728. Re: MACH for a TT

Newsgroup: comp.sys.atari.st.tech

Source record: 48868

You can get the Mach 3.0 microkernel via anonymous ftp. It has no UNIX functionality (it has very low-level basic OS functionality, like VM support and such). The UNIX functionality comes from the BSD emulator (server) that comes separately and requires a BSD license. The GNU multiserver will provide a "free" (in the FSF sense) UNIX environment for Mach (but not real soon, from what I understand).

>comments would be greatly appreciated.

A simple VGA monitor (btw. VGA monochrome is always grayscale) will not
work, because of the different scan rates. That is the horizontal scan
rate. Pictures per second (vertical scan rate) is no so important and is
no problem at all (mostly :-).

A gray scale multi scan (Multisync is a trademark of Nippon Electronic
Corp.) monitor will do.
Multi scan monitors have a scan *range* rather than a scan *frequency*
(horizontal again). If You pick a monitor with a scan range from
14.point.something to 38.point.something, all Youll need is a cable and
a switch (to switch monochrome detect between ground and open).

Go's OS is built from the ground up. But they're just beginning to peddle
their designs to hardware manufacturers. It's not really ``going on'' yet;
they're just talking about it.

Pen Windows is yet another blast of hot air from the marketing masters at
Redmond. They've been working on Windows for most of a decade and still
haven't got the technology straightened out. Just what I *don't* want in a
Dynabook: a buggy, ugly, crash-prone user interface that runs on top of
MessyDos and requires at least a '386 running at 20mHz to be tolerably
fast.

Source record: 48871

A few days ago, someone mentioned a successful upgrade of a 1040ST
using SIMMs. He wanted to post a detailed article about this matter
but I didn't see it (perhaps it got lost, as our system managers
seem to think that atari news are not worth to be stored more than
two days :-( ).
Can anyone tell me more about this subject?
Thanks,

Wolfgang

1733. 520ST I/O problem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-24 22:51:04 UTC
From: BGB100@psuvm.psu.edu
Message-ID: <91083.175105BGB100@psuvm.psu.edu>
Source record: 48873
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have a 520ST with a slight I/O problem: The machine will not read from the SS external floppy drive. To boot the machine, I must have the floppy drive turned on without a disk inserted. After the 30 or 40-second timeout, the desktop appears.
If I try to open the drive A icon, or try to format it (in other words, access it in any way) the system crashes. By crash, I mean that the mouse freezes and only a reboot will free it. I was tracing the 68000 pinouts and it seems like the CPU is stuck in a bus grant state. If I understand it correctly, it seems to be granting the bus, but it never receives it back from whatever it granted it to. The function code outputs signal an interrupt acknowledge and the IPLx lines signal a level-6 (or is that a level-1?) interrupt.
I don't know much about the ST internals as far as interrupts and the way that the floppy is interfaced (is it DMA?). I'm not sure why the CPU has granted the bus to another device which doesn't seem to want to give it back.
Any help/suggestions that I receive on this would be greatly appreciated!

Greetings all...

I have an atari 1040STe and have noticed some strange problems using prospero C on it.. I have 4 megs of ram.. It seems when I compile I get an internal compiler error. The documentation says to contact prospero, but all I got was an answering machine... I do have a registered version of the software. Is there a known problem with Prospero and the STe? If so, is prospero working on an STe version/or patch to the current version? I like the compiler and would like to be able to use it again... Any info would be appreciated...

John

P.S. Prospero C is fully Ansi Compatible...

I don't bother setting the step rates because nearly all the drives can move from track to track in 3 ms. What you need is to feed the STEP signal of WD1772 to 74123N, a TTL, with C & R for 7.0 ms and let this negate the HD-mode. Just another IC and you can forget how to set the steprate.

1737. Noisy SH204

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-25 06:24:20 UTC
From: prism@chinet.chi.il.us
Message-ID: <1991Mar25.062420.4898@chinet.chi.il.us>
Source record: 48877

I have an SH204 20Meg hard drive which is extremely noisy. Since I use my ST mostly for music/MIDI related stuff it is that much more annoying. I have recently started turning the drive off when I'm in the middle of something which I know has no drive accesses. Occasionally I have goofed and forgot to turn the drive on, but I just get an alert box which says the drive isn't responding. I just turn the drive on and let it spin up then click on the retry box. My question is: Is this bad practice? I don't think anything has been harmed yet, and since I don't use any cacheing program I don't see the possibility for problems. I have checked the integrity of the disk with various PD programs similar to UNIX's fsck and everything seems fine. So what do you ST tech experts think? Alternatively, any ideas for getting rid of the noise short of replacing the drive mechanism (which is a Tandon). Any help would be appreciated.

Thanks -

From: wilko@idca.tds.PHILIPS.nl
Message-ID: <1239@idcapd.idca.tds.philips.nl>
Source record: 48878

It is not too difficult to replace these chips. I have done this quite a few times.

What to do: get a good soldering iron (approx 25 watts max)
cut the pins of the LS373 chips
now use the soldering iron and a pair of tweezers (sp?)
to pull the cut pins one by one from the pc board
now use a solder sucker (sp?) to suck the old solder from the
holes.
put in GOOD ic sockets and solder them to the PCB
place the new chips

Off course, as with all good PCB soldering, do it fast. Allow time for the board to cool in between these operations.

The chips: I use 74F373 chips in my Mega 1, but HCT373 should work allright. Anything but SGS Thomson should work (so I am told)

(David M. Baggett) writes:
]The only real reason game writers alter the scan rate is so the game
]play timing won't change. Games run 16.3% faster on U.S. ST's because
]the scan rate is 60Hz here. This means Joust, e.g., is more difficult
]in the U.S. than it is in the UK, something I always make clear when
]comparing high scores with my British competitors. :-)

Don't listen to him folks! He's just a sore loser! :-) x 10E6

]An example of a problem caused by the scan rate difference is the
]treasure room in Guantlet II. U.S. players will notice that the timer
]only counts down to about 4 or so, then the level ends. This is
]because the countdown code stupidly relies on the scan rate being only
]50 frames per second (it counts a second by waiting for 50 vblanks to
]elapse). On U.S. machines 50 vblanks occur in 5/6ths of a second, so
]the timer counts down too quickly, and you only get 16.6 seconds in
]the treasure room instead of the normal 20. (Or is it 25?)

Leaderboard conversely assumes a 60Hz frame rate. I'm not sure how this
affects the game but it really screws up the demo when in 50Hz. The guy
plays bad and doesn't sink the put.

Proper timing should be done using Timer A in the MFP or by latching on to
the system timer (Timer C) which is 200Hz everywhere (a configuration I
believe that should not be changed).

In article <27E4E580.1093@maccs.dcss.mcmaster.ca> johns@maccs.dcss.mcmaster.ca (Conan the Barbarian) writes:
>
>ST BOOK
>--
>CPU: 68000 at 8MHz
>RAM: 1MB and 4MB versions
>ROM: 512KB

<other specs; ..., 20/40/60MB harddrive,...,optional ext. floppy>

Insite Peripherals (San Jose, CA (408) 946-8080) is supposed to have their floptical drive available in volume in April. The drive formats 3.5" barium floppies, with embedded servo info, to 20.8 MB and is also capable of reading and writing 720 KB/1.44 MB floppies. Some of the specs for the drive are: 65 ms average seek, 1.6 Mbps transfer, 1 ms track-to-track seek, 15 ms head settle, and 41 ms latency. It uses a SCSI interface. The OEM price is ~$300.

It's speculated that this will become the standard "A" drive for PCs and hopefully, Atari will offer it as a standard configuration for the notebook. It will add several hundred dollars to the list price, though.

Regarding other aspects of the notebook: 512 KB ROM (Gigantic Tos?), two ram card sockets (hope this becomes standard on future desktop machines too), 1-4 MB ram capability (should have MMU with 16 MB addressability), ACSI port (what differentiates this from SCSI, besides connector pinout?), 128 pin connector WREN compatible (what is WREN? 128 pins give out all the processor signals and the kitchen sink. Does this imply a 68030 model?)

Overall, it sounds pretty good. If Atari has integrated the ST chipset, then future models in the 1040ST form factor would have room for more memory and a VGA-type chipset. Since benchmarks posted here show the blitter chip to give only marginal speed improvements to graphics operations, it should be...obliterated and make room for an upgraded MMU with 24 bit addressability. Did anyone check their 1040 STe to see if the SIMM sockets have an extra r/c address line connected for 4 MB SIMMs?

Jack

1741. Printer Drivers

Hi There,

I've obtained an old Olympus printer that I want to get working on my parents' ST. They mainly use FW+. Could some kind soul out there mail me the format of the printer drivers in FW+, and maybe some tips on how to write them. BTW, the printer is a daisy whll if that makes any difference. Replies by email please, since I don't suppose many other people are interested. I'll forward replies to anyone who would like the info.

Thanks,

Steve- srs@uk.co.stc.icl.oasis

1742. HD and DD floppies (Was: FTP problems)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-25 13:44:17 UTC
From: johnj@hijg.prl.philips.nl
Message-ID: <2631@prles2.prl.philips.nl>
Source record: 48882

I can not solve your FTP problem, but I have some 'news'
about the floppy disk problem.

It is known that HD (1.4MB) and DD (720kB) is not
completely downwards compatible on PCs. And as the same
DD disks are being used for the ST, the same problem goes
for that as well.

What are the problems:

1. HD drives use to make thinner tracks than the DD drives.

2. The material structure of the floppies is somewhat
different. (Note: I'm not an expert in this latter area).

Result:

1. A DD floppy, which is formatted on a DD drive
will work perfectly.
However, sometimes problems arises when the data
written with a HD drive is being read with a
DD drive.

2. A DD floppy, which is formatted on a HD drive
may give problems when used with a DD drive.

3. A HD floppy, formatted on either HD or DD drive
is a good reason for a lot of problems, when being
used with a DD drive.

What should you do, to be most-) lucky:

1. Always use a DD floppy disk.

2. Format it with a DD drive.
(with other words: do not format it as DD with a HD drive)
So format either on a ST (only when you have TOS 1.4 or a TT),
or format it on a PC with DD drive.

3. Write the data on the floppy with a DD drive.

This last step is not always necessary, as I found out that when you
did at least step 1 and 2, you have a pretty good chance that the
data written on the DD floppy with a HD drive, can be read in by
means of a DD drive. However, it may be worthwhile copying the data
to a DD floppy (or Hard disk of course), as you may get problems
in the future.

Hope this helps,

John

No, you should not try to fiddle around with an old and obsolete mtools
version. The latest version - which you should get - does not have the
DUP_FAT define anymore but finds out itself whether the disk has a single
or double FAT.

>Thanks for posting the information. May I ask where you found it? I
>just like to know the sources of these things. :^)

You may feel skeptical, but as the designer of the two machines announced, I can tell you that "TOS ... with handwritting recognition" is FACT, not conjecture. The HCR code will be in the ROMs (and was, in the Demo at CeBIT), and tied into the operating system and desktop such that a gesture in the Menu Bar area will bring up a window (as invisibly to existing applications as possible) into which Hand-written characters are drawn. As you write, the characters are converted to ASCII; when you are satisfied, the characters are sent (via the Keyboard input stream) to the application. This way, _*existing*_ applications will have HCR capabilitites.

The "hooks" to call the HCR system will be available to software developers, so they may call it directly, to recognize ASCII characters, special character sets, or even gestures. This will be part of the standard documentation. In case you're curious, the software is a neural-net simulation.

TRH

[Incidently, "OCR" is "Optical Character Recognition" and "HCR" is "Handwritten Character Recognition"; the former uses the Bit-Map image; the latter uses the "pen-stroke" information directly.]

From article <1991Mar20.210939.18026@ecst.csuchico.edu>, by ekrimen@ecst.csuchico.edu (Ed Krimen):
> Will SIPPs work in an STe? How do SIPPs differ from SIMMs?

> If I have 2 1megx8 SIMMs already in my STe, will 2 1megx9 SIPPs work with
> them to give me a total 4meg?

Disclaimer: I have not actually seen a SIPP yet.....

As I understand it, SIPPS are SIMMS with pins soldered on (or the equivalent). On PCs, they are sold as removeable, in STEs they have been soldered in place of the SIMM connectors. The 1Mx9 SIMMS work fine in STEs, but you will have some modifications to make on SIPPS to make them fit. Have a good look at the ones you are considering, if they look as if they are modified SIMMS, and you think that you can reverse the mod - go for it. Otherwise, don't bother.

Not too helpful, I know 8-).

1749. SS->DS floppy mechs

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-25 21:04:15 UTC
From: BGB100@psuvm.psu.edu
Message-ID: <91084.160415BGB100@psuvm.psu.edu>
Source record: 48889
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have several SS drives which I would like to finally upgrade with DS mechs.

My question: Which mechanisms work (best)? Preferably, I would like to
get HD mechanisms and use them as DS (if possible). It only
makes sense because HD mechs only cost about $5-$10 more than DS.
Will it work though?
My main concerns are about the connecting of the drives and the
reliable operation of these drives.

Any help is much appreciated!

-Bruce.

1750. fcvt/getch/getchar in GCC

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-25 21:09:09 UTC
From: heavy@zip.eecs.umich.edu
Message-ID: <1991Mar25.210909.21762@zip.eecs.umich.edu>
Source record: 48890

I was able to get GCC to work on my system (strangely it would
not work in MT C-Shell, but it works fine from the desktop).
But anyway, what I was wondering, I was compiling some files
that used fcvt (floating point to string), getch (wait for
a character), and getchar (get a char), but when went to link
the files these functions were undefined. I am pretty sure that
GCC on the SUNS has fcvt and getchar (I am not sure about getch),
but does the ST version too? If so, how do I link them in?

Another thing...

When I am linking, does GCC look through all the files in my
lib path or does it only look in a default file? For instance,
if I want to compile a GEM program will I have to specify
'-lgemlib' ?

I'd check what desk accessories and auto programs you are running. I've found that their compilers are very fussy about these things. I can't use Quick St for example or Neodesk 3.0 with either their Fortran or C compilers or I have to reboot after each compile (yecch).

> I didn't see internet addresses of the authors in the Gemini 1.2 distribution.
> To whom does one send bug reports / improvements suggestions?

In my Gemini distribution (which I got directly from Stefan) their addresses
(snail mail and mailbox) were at the top of almost every .doc file; the
README file also gave an Internet (in fact: BITNET) address. Perhaps the
distribution at atari.archive is incomplete?
Here they are as of 10/27/90 (but I got them 2/27/91):

1754. Megafile 44 slowing down...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-26 11:41:01 UTC
From: dick@ahds.UUCP
Message-ID: <1495@ahds.UUCP>
Source record: 48694

I have this problem with my Megafile 44 removable harddisk:
After installing and formatting I partioned a scheme of 20.5/10.5/0.5/10.5
Allthough the manual said the smallest partitionsize should be 1 Mb I tried
making one of 0.5 Mb, and the system accepted this. I did this to install
a small Minix kernel on it. Only the first partition is used for TOS/GEM,
all others are reserved for Minix.

In the Minix corner (drives D, E and F) everything works fine, due to it's
own drivers and (fast) filesystem,
but under TOS I have a severe problem of VVVEEERRRRYYYY slow performance when
I want to ADD a file on the partition and it's still decreasing....

For example, when I copy a file from a flop or from some directory into a
particular folder on the TOS (drive C) partition, the harddisk moves (it
sounds and the orange BUSY light flashes once briefly), and than the orange
BUSY led starts blinking with a frequency of approx. 1 blink/sec for about
(now) 19 times, after which the disk rattles again and stores the file in
the appropriate place.

I noticed that the amount of blinks increases in time: it depends on the
number of files (or something) on the disk.

So far the most annoying problem.
Another problem is that when I copy a folder to another folder on drive C
the first folder underneath the new folder is linked to the root-folder in
some way. Attempts on deletion result in a system reboot. The only way to
remove that wierd folder seems to be the creation of an orinary file next
to the wierd folder, than removing the file, after which the folder can
be removed as well. I have no idea if this problem has any connection with
the former one.

So far, I didn't buy another disk for experimenting.

Maybe it has something to do with my (unusual?) partitioning.
Anybody outhere has any suggestions on this ??????

Thanks in advance,
Dick.

>but does the ST version too? If so, how do I link them in?

fcvt is an internal routine of the SUN. Use sprintf instead to be portable.
getch is a part of curses -- get a curses library. Or use Bconin. (i believe).
getchar should be in the standard library, Perhaps it is only a macro -- did
you include <stdio.h>?

>Another thing...

>When I am linking, does GCC look through all the files in my

Bob,

Thanx for your reply, but I found out what the problem was. It
seems that prospero C wanted the date set. It did not like that fact
that on bootup my date is 00-00-128 00:00:00, so I got a program to
set my date automagically. I have had no problems though using it
with Quick ST 2.10? It works again...

> Specifically, I want to read files from a double sided disk onto
> my Sparc and then transfer them to my ST hard disk via modem (I
> only have a single-sided floppy).

SUN-OS V4.1.1 supports reading, writing and formatting 760K DOS/ST
diskettes directly.

To format use:

fdformat -l -d

To use put:

/dev/fd0 /pcfs pcfs rw,noauto 0 0

into /etc/fstab (usually there already)

Then mount with:

mount /pcfs

Then regular UNIX commands (ls cp mv etc.) will work with the floppy.

Problem:

You have to su root to do the mount /pcfs.

I've been having the same problems with my ST. I figured it was heat,
but I can't seem to find a fan for the thing. I remember a device
called COM-COOL that sat on top of the Commodore 1541 disk drive, someone
recommended that I get this as it fit nicely on a 1040. But, I CANT
FIND ONE ANYWHERE! I need a fan that sits right over the power supply
on the 1040 (where I could probably fry eggs if I wanted to), but the
supply also has to have its own power pack, as I don't want to tax the
power supply any more than I am already.

Shoulda just bought the damned STE. Still might. Anybody know if
Kuma's Occam compiler, Minix, Maple, C Breeze or MT-C shell break on the
STE?

> different. (Note: I'm not an expert in this latter area).

Nope, on both counts. You are not an expert :^), and there is absolutely no material difference between the two disks. This is a big lie from the disk makers to charge way too much for DS/HD disks. The only difference between the two, besides the extra hole, is that there are *sometimes* extra quality check on the DD and HD disks. Actually, even SS disks are the same. If they are given the hole, you can format SS disks to HD with no porblems. They (disk makers) just manufacture a batch of floppies, set aside a bunch to fill the SS order, and then test them for SS integrity. Then they fill their DD order, and test them, then they fill their HD order, and test them, all from the same batch. As the error rate in manufacture is fairly constant, the chances of a SS disk going bad are not that much more than off the shelf HD disks. This is why large fortune 500 corporations use devices like DiskDoubler to save money, and buy SS or DD disks.

1762. Basic hardware upgrade help / resources sought

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-26 23:41:19 UTC
From: slp9m@cc.usu.edu
Message-ID: <1991Mar26.174120.47166@cc.usu.edu>
Source record: 48702
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

While I have been a 1040 ST owner for several years, I have never really been in touch with the ST world. I bought the machine and put it to work on a few simple tasks which it has been performing faithfully for about the past four years. Recently, thanks in a good measure to this newsgroup, I have decided to get more use out of the ol' Atari. As a result of this increased activity, I am now desirous of upgrading the system and am looking for some expert information and/or pointers to same. While I have picked up on related threads in this newsgroup, I am constantly reading assumptions that may or may not be correct into the postings. I really need to start back at square one on a lot of these issues. (I say square one in regards to my familiarity with the particular machine, not computers in general.)

Here are the most urgent issues:

1. Memory upgrades. How to do them. What are the alternatives (I gather from what I read that there's more than one method)?

2. Adding hard drives. What type of drives work? What kind of controller do I need. Who makes a good controller and where do I get one? I prefer to assemble one from a controller, drive, etc. as opposed to a plug & play model.

Then there are some others, not quite as urgent:

3. OS upgrades. I am running TOS 1.0. I assume this means changing the ROMs. Is this true? Where do I get a set? Maybe this should be in the urgent category, but I don't know better.

4. Mouse alternatives. I hate the switches in my original Atari mouse. Are there other mice that work? I just popped the mouse open and it appears to be a simple matter to change the switches, if I can find better ones. If anyone knows of a good source for better switches, I'd appreciate hearing about it.

All advice is welcome. However, I am sure that most of the information I seek has been well documented in a number of places. I would especially appreciate receiving references to books and articles (as well as good places to obtain same). I also need to be advised of recommendable sources for mail order hardware.

E-mail or, in cases where it seems appropriate, posted responses are welcome.

Based on my past experience with this group, I feel completely
justified in offering many, many thanks in advance.

I've found a bug (or at least an unintuitive feature :-)) in the
library supplied with GNU C 1.37.1 found on atari.archive. When I
make a call to stat(), after the call, the address returned by
Fgetdta() is different than it was before the call. Is this a bug?
If so, why would it be desirable for stat() to have this side-effect?

I am trying to port a dBase file library from the IBM...it isn't easy
for me to go in and change a lot of code because it might adversely
affect other portions of this large amount of code that I don't know
about. At any rate, I wrote my own version of fcvt() using sprintf,
seems to work fine. As for getch/getchar, there was only one
reference to them so I took them out...everything seems to be working
fine not (I'll keep my fingers crossed).

Thanks for the info...

Another thing about libraries...if my library has something in it
that calls something else in the archive, to get it defined properly
at link time I have to specify my library twice ('-llibrary -llibrary')
or else it says the second function is undefined...is this suppose to
work this way? Oh, and finally, if I write a GEM program, do I link
with crt0.o and gcrt0.o or just gcrt0.o?

Really? I am studying PDP at CMU [:^)] and would like to know what architecture you are using, and what kind of training set you used, etc. Also what software do you use? This sound way cool! I would love to show this machine to my instructors. BTW, the ATM is going at 40 MPH now with Neural net implemented on Sun Sparcstations!

Posted this time under a more appropriate heading.

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Well I finally got bit last night. The wonderful STE DMA (read harddrive) bug got me. After doing a couple hours of work on the computer with probably 25 or so disk accesses it gave me the "somethings wrong with the disk drive" alert. I then could no longer see the partitions even though the hard disk driver would run. I have an ICD plus host adapter and a syquest drive.
Does this error (the STE DMA problem) always hammer the disk in the same manner? If so, what is necessary to go and recover the drive. No I didn't have a backup as I've had it only 2 weeks and wasn't sure if I liked my layout yet. (Lesson learned though :-( ).
I'll be contacting Atari about a warranty problem in the mean time.

Thanks for any help.

Jim Harres jharres@doc.bmd.trw.com

1770. Video sync disappearing with new HD?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-27 15:20:17 UTC
From: marc@sequoia.cray.com
Message-ID: <043439.10019@timbuk.cray.com>
Source record: 48710

Hi ST-people,

I've just taken delivery of a 106Mb drive from Third Coast Technologies. It's a Toshiba mechanism (apparently) and came with all the usual ICD software. Well, the drive is just fine :-) I've got ACRES of space to play with :-) B*U*T, it would appear that very occasionally the video is losing sync (i.e. the picture goes apeshit and completely unreadable) :-(

This has happened a couple of times, and twice when in the middle of a multiple file copy!! :-o Thankfully, the ST and HD continued talking long enough for the data to get through :-)

So, has anyone out there experienced such a problem when they attached a new HD? I've checked the obvious (cables and connections..) but nothing else is apparent - only the fact that there is a new piece of kit hanging off the back of the ST (520 with 2.5Mb).

Any help or clues would be greatly appreciated. Cheers!

> --
> Roy Bixler
> rcb@netcom.com -or- (UUCP) uunet!apple!netcom!rcb

That's precisely why you have to call Fgetdta(). Usually, you would not
want to mix Unix-type calls (stat()) and TOS-type calls (Fsfirst()/Fsnext())
in the same program anyway, but if you have to, always check.

The reason it changes it is that stat() most likely uses Fsfirst()/Fsnext()
to check the file's status, and it has to set up its own DTA buffer
to do it.

In general, you might want to switch to Eric Smith's MiNT library. It
is an update and improvement on the standard GCC library, and is
also available on atari.archive.

This sounds pretty nifty, but will the machine also allow a
normal keyboard to be plugged in? The HCR interface would be very
handy for portable use, but I can type a lot faster than I can write,
and it would be nice to have the option available.

Hmmm, how do I get this added to the FAQ for c.s.a.st? Ok, I had this problem
also, and called ICD. They were quite familiar with it. They upgraded their
DMA cable (that which connects the computer to the host adaptor) to a nice
snazzy one with little thumbscrews and the ICD logo printed on it.
Unfortunately, with SOME machines (apparently only some Mega's) the new
sexy cable also causes the loss of sync that you experienced. ICD will send
you a new cable for FREE (they ask that you send the old one back) and your
problem will disappear (but you will have the old ugly cable :-) ). You
might wish to call the company you bought the drive from and let them know,
so others won't have to go through this!! See ya!

1774. Composite video on 1040STf?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-27 16:58:13 UTC
From: bright@ccu.umanitoba.ca
Message-ID: <1991Mar27.165813.1728@ccu.umanitoba.ca>
Source record: 48714

I recently came into possession of a Magnavox RGB/Composite monitor, and was wondering whether I could hook it up to my 1040STf. The manual (?!) that came with the machine lists a composite signal on the pinouts for the monitor port (pin 2). Is there actually a composite signal there, or does it exist only in machines that have a built-in rf modulator? If the signal is actually there, do I need some sort of special cable to use it? And is it worth the trouble? (I know that that the display quality would be decidedly inferior to the normal analog RGB, but would I at least be able to play a few color games without too much eye strain?)

Thanks, BBB

Help! How can I connect a Zenith Data Systems ZVM-135 RGB Monitor to an
Atari 1040STE? Here's the ZVM-135's connector pinout:

1 - Negative horizontal or negative composite sync*
2 - Positive horizontal or positive composite sync*
3 - NC
4 - Positive vertical or positive composite sync
5 - Green input
6 - Blue input
7 - Red input
8 - NC
9 - NC
10 - Green feedthrough
11 - Apple X1 Input
12 - Apple X2 Input
13 - Apple X3 Input
14 - Negative vertical or negative composite sync
15 - IBM intensity
16 - Ground
17 - NC
18 - Audio input
19 - Ground
20 - Composite video input
21 - Red feedthrough
22 - Blue feedthrough
23 - NC
24 - NC
25 - Apple X8 input

*NOTE: Composite sync must be supplied to both the horizontal and vertical
sync inputs.

Specifications:

inputs ..... DB-25 type connector
R,G, and B signals TTL level analog positive
Composite - TTL positive or negative
Horiz sync - TTL positive or negative
Vert sync - TTL positive or negative
Ground
Audio - .5V to 1V rms.
Audio ground.
Apple III video - (4)
IBM intensity

Composite video.

This monitor is switchable from RGB to Composite. It has an DB-25 RGB connector and a set of RCA phono type jacks for composite. There was a message floating around (dated 4 Jan 87) that showed how to connect a Sony XBR monitor to an ST and it works (I've seen the result). I realize that I could just use the composite input with the STE but I would like to use the RGB for obvious reasons. Anybody got any clues????

This is the same problem I wrote about earlier in this newsgroup.

It's a known ICD host adaptor problem. Certain DMA accesses or
electrical noise to the ICD HD will screw up the video refresh
logic, resulting in screen image corruption.

The solution is to solder a 22 pF capacitor to pins 12 and 13 of
the DMA IN connector on the host adaptor board.

1778. Re: Mono monitor signal hacking

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-27 22:46:31 UTC
From: adamd@rhi.hi.is
Message-ID: <2981@krafla.rhi.hi.is>
Source record: 48718

In <9103222256.AA06374@uk.ac.oxford.ecs.booth16.ecs> u87rpb@ecs.oxford.ac.uk writes:

>Hi there, does anybody have any idea what might be involved
>in trying to get a mono monitor to think it's a colour
>monitor (ie, to display low and med-res screens in
>greyscale) in *hardware* ?

A circuit diagram and instructions for modifying a SM124 to analog greyscale
was published in ST Computer magazine (German) some time in 1988.
The mono output is mixed from RGB using a passive resistor network as suggested.

>The major problem as far as I can tell would be the sync
>signals. What would happen if I tried driving an SM124 with
>a 50 Hz frame frequency (or 60 Hz, if neccesary)? I guess
>that I'll either get no picture at all, or get something
>like a two-thirds height picture.

If the monitor is not modified internally to cope with the different frequencies
you will fry some of the components because higher currents are involved at
the lower frequencies.

I did this mod back in 1988 and it works (sort of...)
Maybe there were some typos or I missed the corrections in later issues.
I have a SM124 that displays colour modes in mono with 2 major faults.
1) Switched to colour mode the monitor loses all horizontal linearity.
Characters are nearly twice as wide on the left side of the screen than
on the right.
2) Brightness control (and maybe contrast too) is disabled in colour mode.
Colour mode is not very stable until the monitor is warmed up properly.
The focus adjustment is disabled in mono mode (maybe in colour too, it's a
long time since I looked). The actual focus seen on the screen is unstable
and gradually drifts out of focus, suddenly snapping back to correct focus
once in a while. If the brightness is turned down it becomes useable and if
the brightness is turned up it gets really bad.

Summary: If you can find a circuit that works properly then it might be worth
trying. Otherwise you will be better off with a cheap mono monitor that takes
a standard video signal, and mixing the colours and the sync together using
resistors. Some STs have a useable composite sync signal, with others it is
necessary to mix Horz & Vert together over diodes.

Plea for Help: Did anyone get the SM124 modification working satisfactorily.
Get in touch with me if so and let me know how you got it fixed.

Or, try out TURBODOS (it is on atari.archive).

A word of warning though: I used TURBODOS for 2 years, and I experienced
occasional problems with files, and eventually had corrupted files. This
may have just been a bad sector in an unfortunate place, who knows, but
now I've got TOS 1.4, so I'll never know.

If you try it, you'll like it - it speeds things up HEAPS.

I agree that you can probably type a paragraph of prose faster than you can write it out by hand. But what about a mathematical proof or the solution to a physics problem with all its special symbols? I also move the cursor up and down a lot when I type, and that takes quite a bit of time, relatively speaking. I think in some circumstances, I would be more productive if I could use a pen instead of a keyboard. I think I can type a paragraph faster than I can write it, but I think I could write a page faster than I could type it.

From article <1991Mar25.062420.4898@chinet.chi.il.us>, by prism@chinet.chi.il.us (PRISM Interactive Products):
>
> I have an SH204 20Meg hard drive which is extremely noisy.
> [Question about turning drive on and off while in use]

1.) It could happen that the drive needs a reset from the ST
and is also blocking the disk drive, so it may be the case
that you aren't able to save your work. (Perhaps this is a
problem with really old SH 204 Host Adaptors, [Claus Brod ????])

2.) You shouldn't do that to your drive mechanism.

3.) Remove the metal-network covering the fan.
You should also buy voltage regulators (my english is catastrophal)
type 7808 or 7809 and loop them into the fan supply.
These chips lower the 12V power to 8/9 volts.
Be sure that the drive doesn't get too hot and that the fan
always starts when you turn the drive on.

If you have further questions drop me a pmail but please keep
short, INCOMING mail must be paid to the .de backbone.

Bleah. As you may recall, the original NeXT cube used a 25MHz 68030 and
MACH. As you may also recall, the original NeXT cube ran at blazing slug-like
speeds. Even with 32MHz 68030 in the TT, and assuming 80-90% cache hits, I
don't think MACH would be tolerable on the TT. BSD 4.4 would probably be
a better choice, it at least is building on a proven base. Steve Jobs is
hardly on the cutting edge... As for CMU on the cutting edge - how can you
possibly say that with a straight face, with your account on Andrew?

Ok, all ribbing aside... Why MACH? OSF has abandoned it. For Unix today,
there's only a few main things to consider, and MACH isn't one of them;
it doesn't have any major industry support with OSF withdrawing.
OSF, whatever that will look like, if it gets done any time soon, SysVR4,
which is available now, and 4.4 BSD, which is in the wings. Sun and AT&T
are (naturally) really big on SysVR4, current SunOS stuff is trying harder
and harder to be SysV instead of BSD based. (And it's annoying as all hell,
let me tell you. }-) BSD 4.3, surprise surprise, passes the Sys V validation
suite, so it looks like most of the differences (BSD 4.3 vs SysVR4) are
mostly academic. BSD 4.4 offers, among other things, native support of the
ISO networking protocol stack, which would seem to position it Very Well
as the system of the future, as well as the best system for Right Now.

Who knows... (Was I trying to sound authoritative there? Ha, fooled you.
I just don't believe opinions should be humble... }-) What are the issues?
Performance and compatibility. What does "compatibility" mean? Binary
compatibility? (Who is there to be compatible with - the Amiga? NeXT?
Not the Sun, SunOS isn't enough like any of the standard systems anyway.)
Source compatibility? If the various supporters' claims are true, all the
contenders are source-code compatible with each other, or more specifically,
with BSD 4.3.

On another subject... It always makes me laugh when I read about these "real
workstations" and their "graphics hardware," with umpteen zillion features
and "double-buffered graphics!!!!" Wow! Big deal! A 4 meg ST will let you
have *128* buffers, sliced up any way you want! The ol' 8bit let you slice
up a screen display on a per-scanline basis. Talk about manipulation power!
Geeze, these "Real Computer" makers could learn a thing or two from some
"dumb game machines" ... Ah for a hardware smoothscroll on the machines I
use at work...

Well this has happened to me, was helping a friend that has just got
a STE, and was using my Drive connected to a Mega File 30, had
problems with this, the Mega File 30 would not connect to me Drive with
a Supra Host adapter
It had to be Atati to Mega File 30, then my Drive, this I can't understand..

Well after the 3rd STE, all different faults, The Directories of the
Mega File and mine where damaged, This was caused by the last but one
STE , we now have a STE that works..!!

With a use of a program, was able to Fix the Mega File 30.

But the big problem is that the data in the Directory of my 'C', Partition
are moved 2 bytes to the left, a total of say 6 sectors.

Is there a Util that can move the Data back , all the sector editors
that I have tried just over type, there is no insert mode !!

I don't realy want to retype over 3000 bytes..

Can some one Help !!

There is a Mod for this by ICD, they fit a small Cap to the Reset line
in the Host Adaptor, I think that this info has been posted befor
but I can't remember the Cap size...

>

Speaking of CeBIT, what news of TT Sys V R4? I heard it was supposed
to be introduced there, I know Amiga Sys V R4 is there. I am just a
little cynical about an Atari Unix introduction any time soon - come
on guys, make me eat those words! 8-)

> the current directory, etc., but I still can't seem to get it (my
> tabs aren't working properly). Anyone know what I'm doing wrong?

I am replying here since i suspect lots of people are having this problem. Unfortunately, it is due to a small bug in addbytes.c, and is not connected to the termcap entry. i am including some diffs (from Patchlevel 5) and new Makefiles below . There us even a test now (testtab.c included below) for this bug.

BTW: i did send these patches to A.A to be included in the UPDATE sub-dir. somehow, it must have bit the old bit bucket. (i dont have FTP access anymore to send up things directly myself).

> Also, I'm running under msh of
> Mark Williams C fame.)
Shame on you :-) CWRU was the home of gulam, gcc and other neat hacks when we were around. we would have never stooped that low :-) :-)

```
#!/bin/sh

X #if 0'ed out for now till be get the new signal code together
X+
X+ xconsole.c: ers
X+ Re-written to be compatible with lib/console.c. It should now
X+ work over the RS232 (not tested).
X+
X+ addbytes.c:: ++jrb
X+ corrected handling of tabs.
X+
X+ makefile* :: ++jrb
X+ adjusted to use common include file mincl (as per lib etc)
X+ (Delete old CMakefile.*). makefile.?? and gmakefile.?? new
X+ files.
X+
X+ tgetent.c:: ers
```

```
X+ allowed TERMCAP to have a drive specification, and got rid of
X+ the silly "strcmp(TERMCAP, TERM)" test when TERMCAP contains
X+ the definition directly (I think what's wanted is a check that
X+ the name in TERM matches the name in TERMCAP, but it shouldn't
X+ normally be a problem anyways)
X+ also: cleaned up the default definition somewhat.

I would argue that the stat() and all other such functions should have
an Fgetdta() in the 1st line of their code and an Fsetdta() in the
last. That is just good practice. Probably a moot point, since GCC
library is free and you get what you pay for.

[reasons for stat() et al's unfriendly behavior deleted]

>In general, you might want to switch to Eric Smith's MiNT library. It

Yes, but you need MiNT to run a program compiled with that library,
correct? If not, that is definitely a win-win situation!

1791. Atari ST Graphics and C

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-28 20:48:40 UTC
From: ad0834@leah.albany.edu
Message-ID: <1991Mar28.204840.4726@sarah.albany.edu>
Source record: 48731
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

Hello -

I'm wondering if anyone could give me some information on
Atari ST AES/VDI calls. I am using the Sozobon C development system
and I have the bindings for these calls, but I can't seem to find
anything on what the calls actually are! Everything I read seems to
assume that I own a copy of the ST Development Toolkit, which I don't.

Does anyone know of any documentation I might be able to find
online which would explain how to use these calls?

- Thanks

Andy Dickinson

>Help! How can I connect a Zenith Data Systems ZVM-135 RGB Monitor to an
>Atari 1040STE?
[specs deleted]

Whether this will work depends on what sync rates it is capable of supporting;
it certainly has the right connections. Judging by the model number (135) and
supported modes, it almost sounds like the Philips/Magnavoc CM135 which is now
being sold by Atari (minus the composite and digital RGB options) as the
SC1435...

On 5.25 inch disks, DS/DD (360K) and DS/HD (1.2M) use different coercivity
media, 300 Oersted media for DS/DD and 600 Oersted for DS/HD. If you put
a DS/HD disk in a DS/DD drive, you might fry the heads.

1794. ST BibTeX v0.99c 'Features'

Newsgroup: comp.sys.atari.st.tech
Date: 1991-03-29 04:09:31 UTC
From: latornel@unixg.ubc.ca
Message-ID: <1991Mar29.040931.24686@unixg.ubc.ca>
Source record: 48734

The version of BibTeX (0.99c, I think) that I got from
dsrgsun.ces.CWRU.edu about a year ago with the rest of the TeX stuff
that I use has a couple of (for me) annoying 'features':
1) The environment variables TEXBIB and TEXINPUTS may only be
set to a single path, not a series of paths separated by ;s.
2) BibTeX chakes when it finds a path with /s as separators
(rather than \s) in a .aux file.
Both of these make this version of BibTeX slightly incompatible with
the ST port of TeX v2.9. I've worked around them by some creative
script writing in Gulam but I'd like to do better.

Hence, can anyone direct me to a version of BibTeX for the ST that
overcomes the above limitations? I've checked the version at
atari.archive and it appears to suffer from the same problems. If
such a beast doesn't exist, can anyone point me in the direction of
the sources so that I can fix them myself (you'd think I had time on
my hands or something... :-). I know I could start over again from
the MS-DOS Turbo C sources that Jeffery Long (who no longer seems to
exist at the email address given in his docs) used for the port to the
ST but that would definitely be reinventing the wheel (or at least
retreading the tire...)

Online? Not much. The Tim Oren ``Pro GEM'' series should be available
at atari.archive.umich.edu; it's a GEM programming tutorial. You also
should make a point of grabbing all the GEM C code you can find.

(This is a good point at which to insert another appeal for authors
of PD programs to publish their source code.)

Books to look for include the Abacus ``Atari ST GEM Programmer's
Reference'' and Bantam's ``Atari ST Application Programming'' (which is
out of print).

Try your college library and don't forget about interlibrary loans.

Using the Bantam book as a guide, I wrote a set of AES bindings a couple
of years ago and fully intended to complete the job with VDI bindings and
documentation, but set the project aside when Ian Lepore's GEMfast
libraries appeared. Maybe I should have done the docs anyway.

You don't need MiNT, unless your program is doing stuff that TOS really
doesn't support, like forking.

Don't ever use TURBODOS, its VERY buggy, even Atari does not recomend it.

From what I have read, it was compiled with Turbo 'C' Version 1.0,
this I believe has/had bugs in its libraries.

Far better to go and get TOS 1.4, and possibly try a Optomiser
on your Partitions..

Yeah -- I was looking for the Pro Gem series... Does anyone know where
it is? I can't seem to find it on atari.archive.umich.edu...

I did find a program at archive-server@panarthea.sun.com called
fract.c which had some excelent line-a opcode bindings in it.

For those of you who aren't aware, Logitech has come out with the "Logitech ST" mouse - I know that B&C Computervisions in Santa Clara has it ($59.95), and Microtyme advertised it recently in one of the magazines. The Logitech mice for the PC are well-regarded, I have no reason to believe the ST mouse isn't equally nice. It's good to see a major company jumping into the ST marketplace...

This is not the case with 3.5 inch disks, however. Several articles have
been written about the subject in many magazines, and when asked, the
disk manufacturers admit as much. They try to add stuff about non-tested
reliability, but what it comes down to is that the disks are identical,
and if it formats and works O.K., then it has just passed the test. You
save by doing the test yourself.

Well here is my .02 cents worth, why is it that a lot of HD disks fail
when Formating on DD drives ??
I am of the same opinion that HD disks do have a higher Oersteds than
DD disks.

Also if HD disks have been Formated on a HD drive to 1.4 megs,
they can't be used on a DD drive, because of the lower Erase Flux of
DD drives.
They can't Erase the data, because of the higher Oersted of the disk media
This has happened...

>> J. Harris writes about how his ST with ZRAM stops running after a few
>> hours, then when left off for 2-3 hours, boots fine.

>I've been having the same problems with my ST. I figured it was heat,

It could be heat affecting the memory board, heat from the power supply
spreading through the metal shielding and motherboard, or the Atari power
supply is pushing its limits.

By far the most heat in the computer is the power supply. I haven't
calculated the power loss in that supply but it doesn't look very efficient.
There are two choices available. A fan was already mentioned. The best place
in a 1040 for a fan is just to the right of the power supply, blowing upwards.
A good fan would draw most of its air from the side where the power supply is.
Venting slats also have to be opened up in order to get a reasonable airflow.

I chose the other (and probably simpler) solution. I removed the power supply
altogether and fitted a diskdrive power connector where the switch used to be.
Plug in any off-the-shelf power supply and go. All the heat is outside where it
belongs, also there is no danger of accidently pulling out the (DC) power cord
because it is a snap fit. I have room in the computer box now for an internal
hard disk and am not restricted to using the standard Atari PSU with all its
shortcomings. If the standard PSU must be used it can be mounted in an aluminum
box. To avoid RFI leakage it is a good idea to use a screened cable for the DC
power and close with metal the hole where the AC power cord used to plug in.

I hope this will help someone.

From: entropy@gnu.ai.mit.edu
Message-ID: <ENTROPY.91Mar31015905@wookumz.gnu.ai.mit.edu>
Source record: 48647

If I want a program to malloc() some memory (which I want to stay around after exiting) can I then do a Ptermres(0, 0) or do I still have to save the whole program in memory in order to keep that malloc'ed memory around? Or should I do Ptermres(256, 0) to keep only the basepage? Is it legal to only keep part of the program from the top to a certain point in the middle? What is the proper way to calculate the first parameter for Ptermres to keep the whole thing? I'm currently doing Ptermres((base->hitpa - base->lowtpa), 0).

Thanks,
entropy

Ok, last chance (for me :-)). Does anyone have this package? Can I get it (and put it on atari.archive) via email or ftp from anywhere? If not, I am going to try to send a SASE to Germany.

In case you missed out on the posts about this package, it is reputed to be a Unix-like shell for the ST, complete with piping and a collection of Unix-like utilities. I use Gulam a lot, and this sounds even better . . .

This was posted some time ago on comp.sys.atari.st.

--------------------------------------------------------------------------------

Installing a fan on my 1040ST was a sinch. First, I took the sucker apart.
(Warranty??? What warranty??? Oh yeah, do this 91 days after you buy the
machine.) There is a beautiful place to mount the fan between the power
supply and the disk drive right on top of the RF shielding. I just cut a
hole there about 2"x2" and mounted the fan with 4 screws. Since it was
a 12V DC fan, I just connected one wire to the +12V spot on the power supply
and the other to the negative spot. These are labeled on the power supply
so you should have no trouble finding them. Then I put the thing back
together. It fits perfectly. Just go to your local Radio Shack and buy
the fan. I think they have 2 models that will fit in this small space. I
can't remember the part number. It is about 3"x3"x1.5". It is really
quiet too if you put a small resistor inline or a potentiometer to slow the
fan down a bit. Even at full speed, however, the bugger is relatively
quiet compared to a pee cee fan. Bonne chance!

Chris Mauritz

I disagree. The software floating point routines even at 16 MHz could easily take 5 or 10 times as long as the 68881, and you will find that any computer that is halfway serious about graphics has a blitter or graphics engine that does BitBLT.

Yes. Every library call which changes something like the DTA address
should change it back. Most of them do; this one doesn't. I think it
only doesn't under some circumstances, like when the file doesn't exist.

david@doe.utoronto.ca (David Megginson) writes:

>In general, you might want to switch to Eric Smith's MiNT library. It
>is an update and improvement on the standard GCC library, and is

Hello -

Does anyone out there have any experience with the Sozobon C compiler? I'm trying to write a program which uses a good deal of floating point math to produce fractals and I just can't get it to work. The program seems to compile fine, but when I try to run it I keep getting a "Stack Overflow" error. I have ported the program to other systems (UNIX, MS-DOS) and it runs fine, but the atari just won't do it.

Help!

Here are some sites that have a large list of ftp sites available. It is
updated every month. The file is usually called anon.ftp.sites.Z (so you
need to uncompress it, etc). Just type "grep atari <ftplistname>" to get
all the ones that have ST stuff.

> last. That is just good practice.
>
You're quite correct. Actually, in the latest version of the GCC library
this *is* done, except that the function returns prematurely if the
file is not found (i.e. the DTA pointer is messed up if you do a stat()
on a file that doesn't exist). The MiNT library also has this bug at
patchlevel 7; it (and lots of other bugs) are fixed in patchlevel 8,
which is now available at atari.archive.

>>In general, you might want to switch to Eric Smith's MiNT library. It
>>is an update and improvement on the standard GCC library, and is
>>also available on atari.archive.
>
> Yes, but you need MiNT to run a program compiled with that library,
> correct? If not, that is definitely a win-win situation!
>
No, not correct. The library works under TOS, except that some functions
that are MiNT specific (e.g. fork, pipe, spawnve(P_NOWAIT,...)) will
fail -- if you avoid those kinds of functions, e.g. by writing standard
ANSI C, then your program will work fine under either TOS or MiNT.

(NetHack 3.0j was compiled with the MiNT library, for example, and that
certainly exercises a lot of functions!)

1819. MiNT library patchlevel 8

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-02 02:40:16 UTC
From: 7103_2622@uwovax.uwo.ca
Message-ID: <1991Apr1.214016.8916@uwovax.uwo.ca>
Source record: 48659

Patchlevel 8 of the MiNT library is now available for anonymous FTP
from atari.archive. The files:
mntlib8.zoo -- library source code
mntinc8.zoo -- include files; you'll need these!
mntolb8.zoo -- compiled .olb library binaries
may be found in the "mint" directory.

Some fairly serious bugs (spawnve() was putting the wrong value in for
argv[0], and crt0.s was using an incorrect test for whether a program
was launched as a .ACC or .PRG) were fixed, so you probably should get
this if you use the gcc and MiNT. (Even if you don't use MiNT, you can
still use the libraries to compile TOS programs that will work nicely for
MiNT users).

1820. Gulam command-line parsing - how does it do it?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-02 04:00:23 UTC
From: rcb@netcom.COM
Message-ID: <1991Apr2.040023.20267@netcom.COM>
Source record: 48660

I have Gulam version 1.04.05 and just recently noticed some anomalous behavior. For example,

dcp foo bar '-*.o'

passes "foo bar '-*.o'" to the program, while

.\dcp foo bar '-*.o'

passes "foo bar -*.o" instead. I would prefer the latter rendering, but if I leave out the single quotes, Gulam says "'-*.o' failed" and never executes the program. Can anyone make sense out of this or offer any suggestions that would, no matter how the program is invoked, guarantee the second expansion? Of course, this begs the question: is there a (more recent) version of Gulam which behaves more consistently?

Now that we have MiNT and Bash/ksh, this becomes merely a curiosity, but I am curious all the same! Actually, more than curious, because I plan to release this program as shareware soon and would like to have a good answer for Gulam users.

'Thank you for your support.'

1823. Bug fix for Sozobon cc.c (and p2.c ?)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-02 11:12:52 UTC
From: ramaer@cs.utwente.nl
Message-ID: <1991Apr2.131252@cs.utwente.nl>
Source record: 48663

```
There is a bug in the compiler driver for Sozobon C which causes it to append
weird non ascii characters to filenames.
See the source file tools\cc.c , function: chsuf()
just before the `return' it sais
*suf = '\0'
and this should be
*p = '\0'

Bug2: i am not certain about the fix here,
hcc gives a bus error if you feed it
struct kdhjvcsjhzgxcv {
int x: /* colon instead of semicolon */
} abc;
or the following illegal C-code:
f(a)
int a;
{
int xs[] = {a,-a,0};
do_something(xs);
}

The first bur error occurs hcc\p2.c , function: conlval()
i changed
if (nd->e_token == ICON)
into
if (nd && nd->e_token == ICON)
and now hcc reports "need const expr" which is much more informative :-)

Do the authors read this newsgroup, or does anyone know an e-mail address
where to send the bug report?

When you exit a program via Ptermres() everything you have malloc'ed
stays resident even if you say Ptermres(0,0). If you want to keep
your code resident, too, you'll have to reserve it via Ptermres().
It is legal to keep the start of your program resident and throw
the rest away.

I'm new to the net, and I have several questions for you guys out there.
Feel free to answer any one or all of the following:

1) How do you get PC-Speed (yeah, i regret not getting the supercharger) to
recognize the ST mouse as Microsoft?

2) Do you know of a place that buys Spectre 128 cartridges? (I want to sell
mine if anyone wants it, I'll go for Spectre GCR)

3) Anyone wants to buy a Discovery Cartridge with Option 2?
Anyone knows of a place that buys them?

4) Can a parked hard disk withstand the X-ray machines at airports?
I have a Supra 30MB and when I travel for a month or longer, I want to take
it with me, but if I want to get it pass security, they make me open it
and turn it on, which effectively de-parks the head! Anyone out there
knows what to do?

Thanks!
Eli

Try using FATSPEED.prg - speeds up dir search/access - instead of
blinking, it will light up, and stay lit up for a second or two, until it
finds a place for the file.

1829. MAC Printer Driver for OKIDATA 292/IBM Graphics?

I've tried all of the vendors in the GCR Manual and none of them do the OKI 292 and local vendors. Any ideas?

Grappler says they are not compatible with any Atari/Amiga emulators. Has anyone tried them?

Printworks phone is no longer in service and

GDT Sofworks doesn't support the 292 (only 300 and up).

BTW -- I have a printworks printer driver for sale (originally $75) will take best offer.

> and I have the bindings for these calls, but I can't seem to find
> anything on what the calls actually are! Everything I read seems to
> assume that I own a copy of the ST Development Toolkit, which I don't.
>

The following books contain information about the GEM AES and VDI calls.
I think these books are more clear in some ways that the Abacus books.

Programmer's Guide to GEM, by Balma and Fitler, SYBEX Books
ISBN 0-89588-297-3

Compute!'s Techincal Reference Guide to the Atari ST (three volumes)
by Sheldon Leemon, Compute! Books

Volume One: VDI ISBN 0-87455-149-8

Volume Two: AES ISBN 0-87455-093-9

Volume Three: TOS ISBN 0-87455-114-5

The Balma and Fitler book refers to GEM for the PC as well as the ST.
The last three books were put out by the COMPUTE! magazine people (you
may remember the COMPUTE! Atari ST magazine). COMPUTE! magazine might
still have some copies, if your local tech bookstore cannot order them.

Hope this helps.

Hello, Netters!

I'm planning to replace the 20MB ST225 5-1/4" MFM hard disk mechanism
in my Megafile 20 with another Segate model (ST251-1, 42MB MFM)... I'd like
to continue to use Atari's hard disk software, but in order to format the
disk with HDX, I need to modify the WINCAP file so that it correctly represents
the new drive. Anyone know how to do such a thing?

If not, what software do you recommend I format it with?

Thanks,

Steve

It's an optimization. Remember, word-length values loaded into address
registers are automatically sign-extended, so you can store addresses
0000-7fff and ffff8000-ffffffff in only 16 bits. This saves 2 bytes and
a couple cycles every time you reference those addresses. It is also
completely legal/correct.

>00ff8e20 -> ffff8e20???

Dunno, maybe to try to take advantage of the above optimization. It's
also perfectly legal. In fact most of my docs list the hardware register
addresses as ffffxxxx, not 00ffxxxx. Can't think why you'd want to use
4 bytes to store a value when you only need 2, and using 4 slows you
down...
>
>I had this occur when I was working on my app program..MOST ANNOYING.

Nothing to fret about whatsoever...

I have not seen the Bantam book but I found the Abacus one not very helpful.
The Compute "Technical Reference Guide to the Atari ST" series of
books were much better. It comes in 3 volumes - VDI, AES and TOS.

std.disclaimer: I'm not related in any way to Compute! Books but merely
a satisfied customer.

In article <MbvwaYm00VIE08N4wf@andrew.cmu.edu> you write:
>> Excerpts from netnews.comp.sys.atari.st.tech: 25-Mar-91 HD and DD
>> floppies (Was: FT.. John Janssen@hijg.prl.ph (1804)
>
>> 2. The material structure of the floppies is somewhat
>> different. (Note: I'm not an expert in this latter area).
>
>Nope, on both counts. You are not an expert :^),

Yep you are right, I am not a material engineer, just
an hardware and software engineer.

and there is absolutely
>no material difference between the two disks. This is a big lie from the
>disk makers to charge way too much for DS/HD disks. The only difference
>between the two, besides the extra hole, is that there are *sometimes*
>extra quality check on the DD and HD disks.

I think you are wrong here!

There are differences, as I work a lot with both HD and DD floppies and
floppy drives, and their differences drives me crazy-).

It is almost impossible to use HD floppies with DD drives. You are
really asking for troubles.

Ok, I know there are exceptions, dependent on the brand. The only
good results I had were with '3M' HD floppies, but then (see my original
posting) format them with a DD drive, as this seems very important.

I am talking about *REAL* experiences, and that learned me that most
brands have different type of floppies for DD and HD.

You do not need to take my advice, and learn it the hard way if
that's what you want. My advice was only for all other souls around,
who doesnot want to loose important files and waste their time by
finding it out eventually.

Actually, even SS disks are
>the same. If they are given the hole, you can format SS disks to HD with
>no porblems. They (disk makers) just manufacture a batch of floppies,
>set aside a bunch to fill the SS order, and then test them for SS
>integrity. Then they fill their DD order, and test them,

Yep you are right here, but I was not talking about Single and Double
Sided (SS and DS respectively), but about Double Density and High
Density (DD and HD resp.).

then they fill
>their HD order, and test them, all from the same batch. As the error
>rate in manufacture is fairly constant, the chances of a SS disk going
>bad are not that much more than off the shelf HD disks.

And here you go wrong again imo (see above).

This is why
>large fortune 500 corporations use devices like DiskDoubler to save
>money, and buy SS or DD disks.
> -geisha-

Yep you are right again, as i think you are talking about one or
two sides again.

Note: a lot of different computers, a lot of different drives, a
lot of different floppies, all from different brands were involved
in our experience over a period from more than a year.

So again, believe it or not. It's up to you!
I only know the problems we had and the way we found (see original
posting) to continue our actual work (which had nothing more to
do with floppies than just being a storage medium). I just wanted to
share our experience for those who wanted it.

Success,

John

> the new drive. Anyone know how to do such a thing?

Yep. I replaced the drive mech in my Megafile 30 (RLL) with a 120Mb unit.
Basically, all I did was pull the old drive out, plug the new one in and
update the WINCAP file to reflect the new drive's specs. Then formatted
it with HDX-3.01 (I think that's the version #)

If you pull up the WINCAP file in a text editor, you'll see that it has
comments inside it documenting how the different HD specific things are
represented. It's really pretty easy provided you have all the technical
info on your HD type sitting in front of you...

From memory, here are some of the major things you'll need to know about
the new mech:

# of cylinders
# of heads
# of sectors per track
Landing zone
Pre-comp cylinder (Can't remember exactly if this is what it's called)

Of course, I have a _sample_ home brew WINCAP entry at home... :^)

1840. Hardware -vs- Software Scrolling

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-03 19:37:46 UTC
From: wniren@pyrtech.pyramid.com
Message-ID: <150708@pyramid.pyramid.com>
Source record: 48679

Greetings,

I'm planning on designing an application which will use scrolling. I would like to build it on a TT but since it will be a while until the TT's arrive, I would like to get a head start using an older system. As most of you know, the 1040STe and the TT have hardware scrolling while the other models don't.

My question is what's the difference between scrolling routines written for an older system and a new system with hardware scrolling? Would I have to completely rewrite them to take advantage of the hardware or would it be a minor modification?

If it's going to be difficult, I will either buy a 1040STe or wait for the TT to come out.

Any help would be appreciated, thanks.

Swapping mechanisms is a very satisfying way to upgrade you HD space.
I've got a 75 meg SH-204 myself :) (SH-204 w/ a Priam 75 MBy drive)

Hardware-wise, all that must be done is to swich the drives. For
editing the WINCAP file, most of the directions are in the file
itself. The necessary information can usually be had by calling your
drive's manufacturer's techicnal support department. If you don't want
to do that, the Supra drive utilities also work, and have information
for most common drives.

1842. Strange .RSC files for Rufus, Gemini

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-03 22:32:32 UTC
From: Mark.Onyschuk.Of.250/744@f744.n250.z1.FidoNet.Org
Message-ID: <670809257.0@egsgate.FidoNet.Org>
Source record: 48609

Someone posted asking about the peculiar resource files used by programs like Rufus and Gemini. I've done some work with user-defined objects for some in-house and other custom projects. This is what's being done here:

The resource file is loaded, as it normally is. The program then searches the various object trees for objects sporting a particular extended object number. If an object is found then it's ob_spec value is swapped out for a pointer to a USER_BLK structure which contains a pointer to new code that draws the object. It also contains space for a 4 byte word where you can place whatever value you had in ob_spec (if you need it).
This new object drawing code is passed a PARM_BLK whenever the object requires redrawing. The PARM_BLK contains information about the state of the object, the clipping rectangle into which the object must be drawn, etc. One nie feature of the OS is that you don't have to worry about drawing objects in "greyed-out" (ob_state = DISABLED) - this is done for you.
I will pass on source code to an archive at the first opportunity. I've written canned routines to load and automatically patch resources with extended objects, as well as to replace calls such as rsrc_gaddr. To implement some of the things you'll find in Gemini, you'll also have to develop your own form handlers. I have source for this as well.

Best Regards,
Mark

Thanks for the info, Tim. Some of the wincap parameters are nice normal
parameters like number of heads, number of cylinders, etc., but some of 'em
are weird: test pattern? (or something like that) It's different for many
of the drives listed in the wincap, but I don't understand why. The ST225
that was originally in there uses the defaults for all of the parameters
besides the weird test pattern thing.

So far, I haven't received any e-mail responses, but if I do, I'll post
a summary.

>
>Try it and see, eh? }-) The color scheme I chose above gives the
>entire 256 color palette of the PC w/VGA. Try other setups....

I did try out the Fractint you posted ages ago that used flicker palettes, and it didn't flicker too badly. I bet some of the combinations you'll get with the two palettes you posted are pretty terrible though.

I've played with this technique several different times and have never really been satisfied with the results. I'll load up my animation editor and try out color combinations at 60Hz -- some combinations seem to "fuse," i.e,. blend perfectly. In these cases you simply cannot tell that it's swapping between two colors. In many other cases, however, the colors don't fuse at all, and you get horrible, headache-inducing flicker. Mixing 000 and 777, e.g., is totally unbearable, at least on my monitor. I made a little demo that just mixed all combinations of colors in the default NEOchome palette. I got 256 colors on the screen. Yup. But you had to look at it from across the room, with the contrast all the way down, and squinting, or your eyes would turn to jelly and ooze out your head. (Neither was a pretty sight.) :-)

I tried to come up with a formula or set of criteria that would predict which colors would fuse and which would flicker, but never could see a pattern. I did notice that some combinations look OK if the "blending area" is small, but not when you swap, e.g., two solid-color screens. In general, the larger the area, the more flicker. I also wonder if it's monitor-dependent.

Anybody know how to algorithmically pick colors that always blend? Given such an algorithm, one could write a program to find an "optimal flicker palette" -- one where the most combinations possible were rock-solid. This would yield more colors on the screen at once with little flicker and not much CPU overhead. As Howard pointed out, such a screen mode would be superior to Spectrum 512 because each of the N different colors could appear anywhere on the screen. You could probably even do interactive animation (read: GAMES) with this mode, although all your raster operations would be only half as fast.

Even if you couldn't find two palettes in which all combinations blended, finding enough to get 32 solid combinations would be better

than what we've got now: 16 colors, Spectrum 512, or brain-melting flicker.

Maybe if we assigned everyone reading this newsgroup a color combination to try and compiled the results... (Heck, there are only 262,144 different combinations. Aren't there supposed to be tens of thousands reading this group? Well then, that's only, what, 10-20 per person? I'll start the ball rolling with 000 and 001...)

I just installed a Radio Shack muffin fan (part # 273-243B) on my hot ST and I can report that it works like a charm. I left the machine on all night and it's still blowing cool air.

Installation was easy. I went for functional instead of pretty, so the fan is on top of the ST rather than inside. My ST would flake out after a couple of hours and the spot on top of the ST over the power supply would feel extremely hot. If I shut it down for 10 mins, it would work fine. I drilled two holes in the top of the ST over the power supply to screw the fan to the case. I drilled a third hole to run the wires through the top of the case. Then, I cut and soldered these wires:

```
-----red wire ------ / -------- red wire ---

---------black wire --- disk drive
fan power
connector
------ blue wire --- / -------- black wire ---

-------- black wire ---
```

The ST has stayed cool all night and I'll bet this even makes her last longer. Highly recommended for Z-ram owners. This cost me about $15; you can probably find a 3in 12V DC fan cheaper at a real electronics store, but they're hard to find around here so Radio Shack had to do.

You'll have to toggle from 50 Hz to 60 Hz or vice versa in the right
moment. This is done by writing to a shifter register. The switch
direction depends on the frequency that is currently selected for
displaying screens. The right moment is at some time in the last
scan line, so you'll have to install some timer B routine to get an
interrupt in the desired scan line.

This is from memory; I'm not really an expert in things like this.
I played with it once on my ST, and I did some similar hacks to
my ol' 64, but I never completed the work.

The test pattern is used to test the drive for bad blocks (Physical Unit
Markbad).

These differ for RLL and MFM drives; the "worst" byte pattern - that is
the one hardest to store for the media - should be used here, but it
makes no big difference at all.

>I'm wrong, will somebody please post?

You're wrong. The only hardware that can help raster operations is a
blitter, and VDI/LineA automatically takes advantage of that when you
do those operations. But "hardware scrolling" means something else.
It operates on the entire display, not just pieces of memory.

Hardware scrolling means that you have a "virtual display" which is
larger than your physical screen. Imagine a large piece of paper with
a smaller piece of glass on it. Your screen is a "window" onto the
larger display. You can move the window around very quickly, in very
fine increments, and this is hardware scrolling. The point is that you
just bang a few registers rather than moving all 32K of screen memory
to accomplish the move. (On the TT it can be 150K of screen memory!)

(Of course, the piece of paper doesn't have to be as big as the world
you're scrolling around in; it can be just a little bigger, and you can
write the world in strips as it becomes visible.)

Both the TT and the STe can move the window vertically on single-line
boundaries, and the STe can move the window horizontally on
single-pixel boundaries, but the TT can only move horizontally on
8-byte boundaries. This is eight pixels in the 256-color mode, but
sixteen pixels in the 16-color modes, and sixty-four pixels in the
monochrome modes.

Hardware scrolling is only good for limited applications like paint
programs where you want a canvas larger than your screen, or games
where you want to scroll the player's view around in a larger world.

Hardware scrolling CAN be used to make whole-screen scrolling faster.
This is something you do in TOS programs when you're on the bottom line
of the screen and you hit return. But that's another specialized
operation, and it doesn't help such useful programs as Emacs, where
some parts of the screen move and some don't.

You can try to pick colors that have aprox. the same intensity. To this
you can use the NTSC formular :

Luminosity = 0.299*Red + 0.587*Green + 0.114*Blue

I have some code at here that can display 256 graylevels on the mono screen.
(written in C). The program is less than 50 lines long, and features
an advanced errordiffusion ditering algoritm, with a small edge sharping
filter (simple laplace). This have been coupled with a 3 screen 'flicker'
mode. The result is approx. the same as 256 grayscale VGA LCD screens (I
think mine is better, because there is no shadows running around the screen,
but...)
The 3 screens is build to that the 'on' pixels is equally distributed on the
3 'planes' - this avoids flicker.
All this could used with color too, and I think the result would be even
better because you can pick colors which is closer to each other (than on and
off)...
In color mode you can probaly show true-color, but you will need to make some
additional code, to handle interesting subjets - such as picking reprensative
colors from the picture file...

The program IS quick hack, and therefor it only runs on mono in 640x400.
I will send the source to who-ever that is interested...

>combinations. Aren't there supposed to be tens of thousands reading
>this group? Well then, that's only, what, 10-20 per person? I'll start
>the ball rolling with 000 and 001...)

Hmm, let's see, two palettes of 16 colours, each colour has 512 choices.
That's 512 to the power of 32. Which is the measley small value of

49732323640978664215538224814682084010045615079734771744046397689315949701253337553 3056
different palette pairs, less equivalent pairs.

okay, I'll do 2 and 3. :-)

No, but I'll check out the technique a bit more, using the pallette described
in the fractint post.

Warwick.

Hi Walter,
Well so you know, the TT's and Mega STe's are shipping now.
Check with your local dealer as to when they will recieve them. Here is a
buffered message from CodeHead Quarters BBS:

Message : 12250 [Open] 4-03-91 6:19pm

1863. Megafile 44 slowing down...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-05 09:20:08 UTC
From: dick@ahds.UUCP
Message-ID: <1930@ahds.UUCP>
Source record: 48598

I would like to thank everybody who responded to my article
about the slow speed of my Megafile 44.
Summarized, it is clear to me that there are two solutions
to the problem:

1. Use TOS 1.4, or
2. Use FATSPEED.PRG

and
0. Do NOT use TURBODOS

Since some of my programs (like my favorite Mac emulator Aladin)
fail to work with TOS1.4, I think I stick to TOS1.2, so I'll try
FATSPEED if I can obtain it somewhere. Is this freeware or what?
Where to get it ?

BTW, back in the good old CBM PET days, we had the BASIC ROM versions 1.0,
1.1, 1.2, 1.4 etc (all totally incompatible - Tramiel Systems marching on...)
all online, selectable with a rotary turnswitch on the front of the PET.
Maybe I switch back to that principal someday >:-((

Hello World,

I am looking for the Atari Version of LOGO. I think that it is PD, but I can't seem to find it anywhere (Haven't really looked that hard). Does anyone out there know where it is/if it is PD? I need it for a programming project.

Does anyone know where I can get a graphical version of the Backgammon game for the ST?

Please mail me relpies, as our news reader is very flakey and most messages are junked....

Thanks, Andrew

1865. HD ST251 in SH204 doesn't start

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-05 14:39:42 UTC
From: sievert@gypsy.ims.fhg.de
Message-ID: <68@gypsy.ims.fhg.de>
Source record: 48599

Hi!

Some month ago I bought an old SH204 housing with a Seagate ST251 40MB HD.
This combination doesn't start properly. After power up it never starts,
so I have to switch it off and on again and again, until it works.
Once started, it operates ok, no problems at all.

This is a problem between controller and HD, I don't even have to connect
the ST to watch it. I even used an logic analyser to find out about it,
but found nothing.

The procedure is this:

After power up, the HD performs its selftest. this ends up in moving the
heads to track 0 and reporting READY\. Than the controller moves the
heads slowly up some tracks and jumps back to track zero. Here it stopps
for some 10ms "thinking"...
Now comes the point: Either the controller works on by moving the head
upwards about 8 steps of about 10 tracks (numbers may be wrong)
--- or ---
it doesn't.

If it doesn't, the ST wouldn't recognize the HD and boot.

Can someone give me a hint or a heck to solve this ***** problem?
I'm just about to smash it ...

-Clarance

As far as I am aware, you get the cable, board (DMA<->SCSI etc.) and software. I think you get a clock with this adaptor too. Finally, make sure you don't get bitten by the `famous' (apparently) ICD DMA noise problem - I did :-)

BTW, thanks to all those who replied to my query about this (Mickey Boyd, Rana Dutt, Roger Sheppard, John Kawakami) - it's getting sorted out as we speak...

1869. How store extra data at the end of an executable?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-05 21:40:23 UTC
From: erik@mcrware.UUCP
Message-ID: <5796@mcrware.UUCP>
Source record: 48605

Here is what I would like to do. I would like to append a picture file to the end of my executable file. In this case, the extra data is a picture file that is the menu for my program. Once a program is loaded into memory, is it closed and all file offset information lost, or is there a way I can start reading data from the file where the program data left off.

If it matters, I am working in C with assembly when required.

Thank you,

Erik R Johnson

I'd like to get hold of keypresses. It's easy to get hold of mouse motions by inserting your own handler in place of the mousevec in the struct returned by XBIOS' kbdvec function. But how do you get hold of keypresses? Must you intercept the keyboard packet handler and interpret all the packets?

Thanks in advance,

From: the_pawn@tahoe.unr.edu
Message-ID: <5985@tahoe.unr.edu>
Source record: 48611

My internal floppy mech. in my 1040STf is now dead. My question is
does anyone out there know where to find a replacement mech. for the
older ST's (The drives with the WIDE eject buttons) or is such a
search considered futile? Also, can anyone post (or e-mail direct?)
a list of drive mechanisms that should be avoided (ie. Chinon).
Suggestions for the newer floppy mechs are also appreciated since it's
looking like I'll have to get one of those. Unfortunately, if I do,
I'll have to take a pair of snippers to my ST case for that tiny button.

Thanks in advance...

Sterling, VA 22170

This mag impressed me enough to buy all the back issues (3 years worth). Lots of good reviews, technical stuff, the best PD library (they replace dated versions of stuff for free). The rest of the US ST magazines are not worth the paper they are printed on, IMHO. I really recommend that you at least get a sample copy (their phone number is (703)450-4761). This magazine has saved me a lot of money with their honest reviews.

Try:
1. Generate your .PRG (eg. with C or M2 linker, etc)
2. Have a separate program to:
a) Fseek to the end of the .PRG file
b) append any other data

Your program should Fseek backwards from the end of the .PRG file, to the
start of the additional data, then read it.

This will work, provided the additional data does not confused the loader.
If it does, then I'm stumped, I'd assume the loader ignores additional data.

>data from the file where the program data left off.

I've done this successfully storing a SMALL amount of data holding default
settings for a printer-driver program. It could probably be expanded though.
The main point is that an executable file is like any other; it gets loaded
into memory to run, but if you can find it on disk or wherever you can modify
it at will, as long as you don't damage it.

What I did was to start the program with a function which is never called.
This contains any "password" you want, encoded into an ASM block.
So:

```
my_data(){
asm{ DC.B "The password"
DC.B "Enough space to store what you need"
} }
```

The program opens its own file (the_prog.prg or whatever) and searches for
the string "The password"; since function my_data is near the start, this
doesn't take long. Then the subsequent data can be read or written. The data
and password, which obviously aren't executable themselves, never screw
anything up because the function is never called as a function. It's a kludge
but it's fairly simple and it works.

ONe problem for the stated application is that the program would have to know
how to find itself and what its name is, in order to do the searching. Perhaps
you could use the principle of a non-executed block to store your file as data,
and give the program a pointer into it?

If you want to know if the key is up or down then I'm afraid the answer is yes. If you just want to catch the key (scancode and ascii) entering the keyboard buffer then intercept the ikbdsys vector with a routine that checks the buffer pointers before and after calling the original. If the buffer pointer has changed then a key just entered the buffer. One use of this is to program macros on the function keys. (ie. If F0 enteres buffer, remove it and place something else in there)

Just to make sure I understood things correctly: So I can write a program that
allocates memory for, say, a cookie jar and then terminates via Ptermres(0,0),
then the program will be removed from memory but the malloced space is ready
to be used by other programs running later?
Is that space EVER freed?

I've got this 520ST hanging around, gathering dust because the floppy drive is broken. Thought I'd ask around and see if I can get enough info to fix it. Here's the problem... turn on the computer, floppy (internal, single sided) light comes on (can't tell if the motor spins)... won't read the floppy ... after typical delay (40 seconds, I think), desktop appears, but the floppies give error message when I try to open them. What I know for sure:

1. The drive mechanism itself is OK (replaced it with a known working drive)
2. The floppy I'm testing with IS formatted (done on my 1040ST)
3. The 520STFM used to have a RAM upgrade which failed (probably unrelated to this problem).

My guess is the floppy disk controller chip. My next step will be to desolder it and replace it (I suppose it's easy to identify). Any other suggestions would be most welcome (I've tried re-seating all the chips I could find).

Thanks
cscullio@ncratl.AtlantaGA.ncr.com

In a GEM program, use appl_tplay to simulate a keyboard event.
In a TOS-only program, you might find it sufficient to manipulate
the BIOS keyboard buffer accessible via some function (I forgot
the name, sorry). The appl_tplay method, however, is cleaner
and should be preferred.

>I'd like to get hold of keypresses. It's easy to get hold of mouse

>hold of keypresses? Must you intercept the keyboard packet handler
>and interpret all the packets?

Alternatively, you can watch the BIOS keyboard buffer contents
accessible by the abovementioned, still unnamed function 8-)

This space stays resident till MIN(end of time, next cold/warmstart).
Ptermres() hides all memory blocks you allocated, i.e. you won't find
it in any of the two memory lists (memory free list or memory allocated
list). So you can't do Mfree() on it. If I'm wrong here, Allan Pratt
will certainly correct me in an instant 8-)

This seems like exactly my problem. Since the ikbdsys, address of which is also returned by kbdvec, reads the keys off the UART there really does not seem to be any other way of doing that. The difference between the mousevec and the keyboard routines, is that the mousevec is passed the address of the mouse packet, whereas the keyboard routine is not (or do I have that wrong ?).

Perhaps you could intercept the actual interrupt routine in some way ?

>Some month ago I bought an old SH204 housing with a Seagate ST251 40MB HD.
>This combination doesn't start properly. After power up it never starts,
A hard disk draws a lot of current when is first turned on. If the power
supply is not big enough to handle the drive then you will see problems on
powerup. This frequently happens when people upgrade a drive mechanism (ie:
putting a 40 meg drive into an SH204) without upgrading the power supply (or
checking it to see if it is sufficient).

Try powering the drive off of a bigger power supply (mostly the +12 has to
have more current drive) and see if that doesn't cure your problem.

It is an ACSI (Atari) to SCSI Adaptor, which may include a real time clock. And it's worth its money.

You should consider using this adaptor with a Quantum Pro-Drive, speedy, nearly no noise, 3 1/2 inch. Works fine.

Disclaimer: I have no connection to ICD or Quantum.

Greetings, Bjoern

>
> Is there any (legal) way to simulate a keypress from inside
> a program.

This is not too legal, but it works:

'io' is Iorec(KBD);
'bits' are the special keys
'scan' is the keycode to be written
'k_xx' are the Keytbl() scan->ascii tables.

```
void queue_key(unsigned int scan, unsigned int bits)
{
unsigned int next;
if( ( next = io->ibuftl + 4 ) >= io->ibufsiz )
next = 0;
if( next == io->ibufhd )
return;
*(int*)((char*)io->ibuf+next = scan | bits << 8;
*(int*)((char*)io->ibuf+next+2) =
( bits & KB_CAPS ? k_cl
: bits & ( KB_SHIFTL | KB_SHIFTR ) ? k_sh
: k_us
) [scan];
io->ibuftl = next;
}
```

Hope that helps,
Bjoern

I'm in the process of attempting to recompile MicroEmacs 3.11 to make some changes (remove mouse support so I can use within a CLI, for one). The source code appears to expect Mark Williams C, but I'm using Sozobon (also have Alcyon). So far I've seen two compilation (haven't tried linking yet) errors: the structure DMABUFFER is expected in stat.h, the Sozobon stat.h doesn't reference it, and "aesbind.h" is expected, which also isn't in the Sozobon or dlibs distribution. Any ideas how these can be compensated for or where I might find AES bindings (are they in another .h file?)

What other things should I watch for when porting from one variant of C to another, especially when I don't have documentation for the original target?

From: aking@bbn.com
Message-ID: <63607@bbn.BBN.COM>
Source record: 48627

I've written a program which uses GEM windows, and I would like to add printer capability to it. The simple thing of "print screen" lacks the resolution I need. How do you change such a program to redirect its output to the printer rather than the screen?

I've scanned the developer's docs and Lasar C manual and nothing's popped out at me. I suspect I should open a virtual workstation as a printer class device rather or metafile than a CRT screen, and then install GDOS and the appropriate printer driver. However calling open_vwork with a class of printer=21 have not moved the the output of my program from the screen, as I suspected it would.

Thanks

Allen King

Message-ID: <1991Apr9.105007.10362@newcastle.ac.uk>
Source record: 48629

Hi, Having been sent some gif pictures, I decided to view them on my ST.

I looked around the PD site and found a few viewers, and also GIFSPC and SPLINDEX.

When the gifs were viewed using FASTGIF the pictures came out ok (In 16 colours) but I decided I would like to see them in full colour glory and so feed them through GIFSPC and viewed the result on SPLINDEX - The result was a completely messed up picture. Could be the convertor me tinks and so tried BGIF. The resulting SPU picture was better but still not perfect as it was still corrupt in places, (odd lines missing etc)

Has anyone else had this problem, if so has any one cured the problem. what is the problem. etc etc etc?

My Machine is a 520STFM with 1.02 OS and 2.5M of memory

> or where I might find AES bindings (are they in another .h file?)

The DMABUFFER is a 44-byte buffer used by Fsfirst() and Fsnext(). The MWC
stat.h file includes a typedef for it; dLibs includes it directly in the
definition of the stat struct. The MWC definition provides some access
to internal GEMdos memory (the part dLibs identified as ``reserved
field. DON'T TOUCH'' but you probably won't need any of that.

The dLibs source code should have some examples of using its stat
structure. I think the rule of thumb is to get the old DTA pointer
and save it, declare a new DTA buffer, Fsetdta(), use it, then
restore the old buffer with Fsetdta.

The MWC aesbind.h file declares the values returned by AES functions
-- all are ints, so you don't have to worry about that -- plus a couple
of peculiar structure typedefs: Rect (four integers), Prect and Mouse
(both four pointers to ints). The Mark Williams documentation uses those
structures in a (probably vain) attempt to make GEM function calls more
readable.

> What other things should I watch for when porting from one variant of C to
> another, especially when I don't have documentation for the original target?

I can't think of any really bizarre things that you'll run into going
from MWC to Sozobon. If you go in the opposite direction you'll need
the dLibs source code handy, because Sozobon's library is far more complete
than Mark Williams', especially in the string-handling functions.

>and all file offset information lost, or is there a way I can start reading
>data from the file where the program data left off.

Although I havent tried, it should be possible to simply append the picure
data to the end of the file without disturbing the program. The location of
the picture can be located by looking at the program header, or by simply
loading the last 32K or whatever.
After program load, the entire program file should be in memory and should
remain there during program execution (I dont know what will happen to
relocation info, though, but I cant imagine it will be freed). Look at the program's
basepage, and you will find some pointers to the text, data and bss segments of
the program plus the lengths of these segments. The picture data should be
just behind.
for more info, consult the documentation of the basepage structure.

Good luck
Okami-san

>Dave Johnson

I had these problems, too.

I got several GIF->SP? converters from atari.archive but no one was ok.
GIFSPC has the effects a described above. It seems that the color
computation is buggy. I tried to convert the baywatch4 GIF pic and
noticed a wrong background color in some areain the SPC pic. It should
be light blue but was dark blue. And the same with Erikas body 8-(...

BGIF seems better as GIFSPC, but doesn't use all y-resolution. The
resulting SP? pics are teeny weeny itsy bitsy ones.

VGIF has a build-in converter which seems to be the best of them, but
(my version) converts only the top left edge (320 x 200) of the picture.
What a mess if you want the baywatch* GIF pics convert to SP? 8-((

I have coded a good RGB2SPU converter, but 'til now I have *no* GIF2RGB
converter. I 've started last month, but got no result 'til now. The
GIF pic format is very *tricky* 8-(((

BTW: I'm using a MEGA ST2 with TOS 1.4 (new notation: 1.04) and 4 Megs

Any comments, ideas?

Source record: 48635

Hi there !
I've finally got a _real_ TT030, and have just recompiled the entire mint-library (patchlevel 8)
with -m68020 and -m68881 flags. The -m68020 flag did really work, and things does go along a bit
faster, but I'm having real trouble with the math-coprosessor. If i write floating-point code and compile with the -m68881 option the program tends to bomb 2 out of 3 times. It bombs every time if I have the processor-cache on. The code does execute faster, so I guess the 68882 is being used.
Then I saw there was a file on atari.archive named gasfp.zoo, is this some special version of gas
that is needed for the co-processor to work ? or am I missing something else ??
The most obvious thing would be that the libraries only support 68881 as peripheral I guess, as in the megas, anybody know this for sure ?

Oh, and there's no way that I could make emacs.ttp work anymore :-(

> but none come with GNU C and GNU RTX library...do I need
> to use these include files to write a program using RTX?

on atari.archive you should find rtxbind.zoo (or something matching *rtx*), in the gnu area. it contains the bindings for gcc and rtx, and an example (dining philosophers). if its is not at Patchlevel 2, you also need the update, that should be available there too (i cant check file names etc, as i dont have ftp access anymore).

cheers,

Try pointing your soldering iron at a different target. I had a similar problem with our club's 1040. Turned out the problem was a bad solder job on the PS' circuit board. Try resoldering the points where the leads from the transformer connect to the board. Based on what I saw with this unit, I would likely re-solder all PSs I come in contact with... To be sure, check the 12V to the drive; you may find that it is either low or non-existant.

Good luck.

Hello,
I am looking for a controler for a pair of MiniScribe 6085 hard drives
they are mfm type drives with the cir. board made to the bottom, they
have two edge connectors one is 20 pin, the other is 34 pin, nay help
would be nice.

Advance thanks in <<

Greg

I have been LaTeX'ing on my ST for about 3 years now, and have always dreamed of an ST program similar to Fig for Suns! But such a beast I have never seen, up till now!

I just downloaded from forwiss.uni-passau.de in the /pub/atari/tex directory a great looking file called texdraw.lzh. I unlharced it, and found that the majority of the document and program is in German.

BUT DOES THIS PROGRAM LOOK GREAT!! Do any of our bi-lingual net readers know if there are any plans for an English version of this program??
I only know that if such a beast exists, or is in the planning stage, many of us ST/LaTeX freaks would love it!! Anyone willing to check on this??
How about just an english version of the .rsc file??

Heck, this thing is so impressive, I may learn to read German just to use it! I'm talking one very slickly done piece of graphics/TeX tool here!

>Is there any (legal) way to simulate a keypress from inside a program.

You find the address of the raw keyboard buffer using the XBIOS function iovec. Keyboard scancodes can then be inserted directly into the buffer. You will want to disable interrupts or otherwise stop the real keyboard input while you are simulating keypresses (if you prefer not to have mixed input). Whatever you put into that buffer will be picked up by the BIOS the next time(s) it gets some input from the keyboard device, just as if it was actually typed in.

In <1991Apr8.160108.22367@etek.chalmers.se> fabian@etek.chalmers.se (Martin Fabian) writes:
>In <1991Apr6.000637.20676@jato.jpl.nasa.gov>, vsnyder@jato.jpl.nasa.gov (Van Snyder) writes:

>This seems like exactly my problem. Since the ikbdsys, address of
>which is also returned by kbdvec, reads the keys off the UART there
>really does not seem to be any other way of doing that.

>Perhaps you could intercept the actual interrupt routine in some way ?

This can be done but is not to be recommended. This is the system programmer's domain and is the right place to modify the keyboard handling systemwide. This is for instance the only sensible place to patch in a national keyboard routine. If applications programmers start fiddling with this we might end up having to replace the ikbd chip to get tamper-proof keyboard handling. This is Iceland, we need access to weird key combinations within other peoples' programs, to get the full range of characters even when programs read the scancodes directly.

Please stay away from patching the ikbdsys routine unless:
1) you fully understand the implications of the changes made, this includes certain timing constraints.
2) the change does not destroy or undo any previously applied patches.
(but you don't know what these patches are, so leave it alone).
The normal way of modifying keyboard input is by patching the BIOS bconin routine. The scancode is also returned here so you can do just about anything you like with the keyboard input using bconin.

1905. Need brief help from Atari Lattice C user with "Malloc"

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-10 04:57:20 UTC
From: xanthian@zorch.SF-Bay.ORG
Message-ID: <1991Apr10.045720.28081@zorch.SF-Bay.ORG>
Source record: 48497

Hi, sorry to butt in on the wrong side of the Amiga/Atari free fire zone, but I need a little help from someone familiar with the Atari version of Lattice C.

I'm trying to bring up a version of the Boyer/Moore sublinear time string search algorithm on a BSD 4.3 Unix box. Unfortunately, from my point of view, the sources I have are an Atari ST port that was done without #ifdef conditionalizing, and I'm having trouble understanding a small piece of Lattice C code, specifically, what some calls to Malloc are doing. My (Amiga) version of Lattice C doesn't include the "Malloc" call, so my own docs are useless.

The code looks like this:

```
|=| #include <stdio.h>
|=| #include <osbind.h>
|=| #include "bm.h"
|=| #include "extern.h"
|=|
|=| static void loinit();
|=| static int loread();
|=|
|=| Execute(DescVec, NPats, TextFile, Buffer, inbufsiz)
|=| {
|=| ...
|=| /* initialize */
|=| loinit();
|=| ...
|=| } /* Execute */
|=|
|=| static char *lobuf, *lopos;
|=| static int lobread, loeof, lbsiz;
|=|
|=| static void loinit()
|=| {
|=| int newsiz;
|=|
|=| if (lobuf == (char *)0) {
(1) |=| lbsiz = Malloc(-1);
(2) |=| while (newsiz = lbsiz & (lbsiz-1)) {
|=| lbsiz = newsiz;
|=| }
(3) |=| lobuf = (char *)Malloc(lbsiz);
(4) |=| if (lobuf == (char *)-1) {
|=| fprintf(stderr,"bm: memory allocation failed\n");
```

```
|=| exit(1);
|=| }
|=| }
|=| lopos = lobuf;
|=| lobread = 0;
|=| loeof = 0;
|=| }
```

Elsewhere, _mneed is set to 30000 bytes, which, I understand, establishes a minimum heap space available by setting a global for the compiler.

Pretty obviously, after you stare at the (rather clever) loop at (2) until your eyes cross a bit, what's going on is an allocation of a block sized a power of 2 the largest contained in the value returned to lbsize by "Malloc" at (1).

Questions:

a) Is the "Malloc" call at (1) getting the largest available block in the operating-system-maintained free list?

b) If not, what's going on with the "-1" parameter (and is it being promoted to a long integer behind the scenes, while I'm asking)?

c) Could the call at (1) return a value _larger_ than "_mneed" is set?

d) I'm used to seeing (lower case) "malloc" return a zero (== null pointer) when allocation of the requested size isn't possible. Why is the test of the value returned by "Malloc" at (3) done against a pointer cast of "-1" at (4) instead?

e) What would a zero return have implied that a "-1" return doesn't from "Malloc"?

f) What exactly is the "-1" return telling me about an allocation failure?

Email responses only, please; I really try to keep out of newsgroups where I have no business, since I tend to answer 10% of what I read otherwise.

;-)

If this is something everyone but me reading this doesn't already understand, email a request for a summary of responses, and I'll gladly post one back here.

Kent, the man from xanth.

Source record: 48640
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Speaking of texdraw.lzh, it is also available from atari.archive. The copy I downloaded would test out well, all the members would test okay, but the archive as a whole would finish with a CRC error. Lharc on Unix and Lharc version 1.02, 1.13, and 1.13.8 on my ST would all error abort. Only lharc 1.13 on a PC accepted this file correctly!

Are the ST/Unix version of lharc still bugged?

[stuff deleted]
Perhaps the problem isn't the converter, but the slide show - program.
Spectrum slide shows are very tricky, most of them run only with 50 Hz or 60 Hz
monitors (that was an exclusive or!). I got a similar problem with GIFSPC and
SPSLIDEX, which was written for 60 Hz. The code in 50 Hz slide shows needs an
additional 'NOP'.

1909. random key repeats...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-10 12:38:26 UTC
From: bointon@kcl-cs.UUCP
Message-ID: <2171@xenon.kcl-cs.UUCP>
Source record: 48508

I have recently started to have an odd problem- occasionally any of the keys esc, 1, 2, 3 or 4 will suddenly start to repeat at the full repeat rate. It can be stopped by pressing escape. The problem has occured on 2 STs using similar setups.

Programs installed are :

UIS III
AMCLIGHT
Fatspeed
Pinhead
Turbo ST
foldrxxx
Cons_fix
Headstrt
Formdoit

Accessories:

Harlekin
Callfsel
Treeview

It seems to happen at any time- on the desktop, in dialogues and in applications. Gemini 1.2 is running too.

Any bright ideas?

Marcus Bointon.

1910. M-Tools, where to ftp from?

|>
|> Can you (or someone) please post a description of this problem?

I posted a query a few weeks back which described a problem with my new HD.
The video display appeared to lose sync (i.e. go haywire) intermittently. I was
told by fellow netters that this was due to `noise' generated by the ICD host
adaptor, which was interfering with the video circuitry.

This is a known problem at ICD. Apparently they either ship you a different
DMA cable, or suggest connecting a 22pF capacitor across pins 12 and 13 of the
DMA IN connector.

Seasoned netters: please flame if I've misunderstood any of this :-)

1913. Me and My soldering iron II

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-10 17:30:35 UTC
From: cscullio@ncratl.AtlantaGA.NCR.COM
Message-ID: <18502@ncratl.AtlantaGA.NCR.COM>
Source record: 48499

Many thanks to John, Dzung, Mark, and Derrick for their helpful input to my flex drive problem. Upon their advice, I checked power, MMU and GLUE chips and found all were OK. The computer still won't recognize the floppy drive during powerup (or any time, for that matter). I hooked up an external drive (genuine Atari), which went unrecognized, except for its existence (i.e., trying to format drive B did not result in the prompt to insert a disk as if only one drive existed). That shoots the cabling theory as well. I'm left with the floppy controller chip (WD1772). I don't want to mess around with my one working ST, so I need a source for this chip. Any suggestions?

P.S. I did listen very carefully and, yes, the drive DOES spin when accessed and the light DOES come on, but that's all.

Source record: 48514

I know this is probably on the most frequently asked questions list (or should be), but I need to expand the RAM on my 1040ST. Does anybody have any recommendations on what RAM upgrades are available, which are the best bets, or if there are any clear cut winners, or maybe some that I should avoid? Are there any that allow you to upgrade even more with SIMMS later on down the line? I would appreciate any input on this matter.

I never thought back in the days when I "upgraded" my TRS-80 to a whopping 48K (full capacity) that I would ever ever have a computer with 1 meg... and still not have enough memory to do what I want (grin).

Lots of replies on a previous posting in this group, concerning problems
I have with my megafile 44 harddisk pointed out that I have to migrate
from TOS 1.2 to TOS 1.4, or use FATSPEED.PRG instead.
Since I prefer trying the latter option first, I would like to know where
I can get this program.
Someone mailed me it should be on some usenet-accessible board.
Can anyone mail me details about the full path (and type of info-server,
if appropriate) ?

Thanks a lot in advance everybody!

Dick.

What kind of error message do you get when opening the floppy?
To make sure this is not a diskette problem, try to boot without a disk
in the drive. Then insert a blank disk and format it. Check if this works
and if you can access the so-formatted disk (write desktop.inf to it etc.)
Get an external floppy and use it to read a) your original boot disk and
b) the disk formatted with the internal drive. If it reads the boot disk
but cannot access the newly-formatted disk, the r/w head might be out of
alignment.
Using the external drive correctly proves the controller is Ok of course.

Good luck
Okami-san

The problem is again that it's a real hard job for a prg to find it's
own executable. Dont rely on it being in the current directory. Dont rely
on finding the name in argv[0]. The problem in this case is primarily to
find the data in memory, since there is no reliable way to find it on the
disk.
There was a discussion in comp.lang.c about finding the executable file some
time ago, and it convinced me that this is not generally (sometimes even
not at all) possible.

I've notices lots of posts lately with odd termination of lines
(looks like a backspace character instead of a carriage return-linefeed
combibation). What could be munching up the CR/LFs at the end of each
line? I find these message are usually interesting in content but I
have to turn my vt-100 mode off on my "dumb" terminal and look at these
messages with all control codes visible to read the screwy messages.
Anyone else have problems with messages reading improperly (looks like
missing lines, and an odd character at the end of most lines)???

> its output to the printer rather than the screen?

Install GDOS & a printer driver, using device id 21 + fonts.
Then the following piece of source should bring what you expect:

```
int h,i;
int in[11],out[57];
int p[10];

appl_init();

in[0]=21; /* DEVICE ID */
for(i=1;i<10;in[i++]=1);
in[10]=0; /* NDC */

v_opnwk(in,&h,out); /* NOT VIRTUAL !!! */

if(!h)
{
printf("h: %d, couldn't open\n",h);
appl_exit();
exit(1);
}

v_arc(h,5000,5000,2000,0,900);
v_clswk(h);

appl_exit();
exit(0);
```

Hope that helps,
Bjoern

DMABUFFER is MW's acronym for DTA (passed to GEMDOS Fsetdta()).

Have no Sozobon at hand, try obdefs.h / gemdefs.h.

So short, Bjoern

Works, but my confuse future loaders, etc.
Cleaner method:
Define a field in your programs data segment.
Taking the offset (in the running program) from your
textseg to the fields address you can figure out where
your data is on disk. (offset + sizeof(PROGRAMHEADER)).

Hope that helps, Bjoern

> until your eyes cross a bit, what's going on is an allocation of a
> block sized a power of 2 the largest contained in the value returned
> to lbsize by "Malloc" at (1).

I got told that what this loop was doing still wasn't clear, even _with_ staring crosseyed at it, so here's an example:

Say the value returned to lbsize is 0010001001 binary; then what the repeated minus 1's and bitwise ands do is:

```
0010001001 a
-1
0010001000 b
a & b = 0010001000 c
-1
```

0010000111 d
c & d = 0010000000 e <---- This is the last one saved into lbsiz...
-1
0001111111 f
e & f = 0000000000 g <---- ... because this one is "false", so the while
loop insides don't get executed for it.

i.e., they "eat" the less significant "set" ("1") bits off from the right;
but since you save the last non-"false" value after an &= step, you have
in lbsiz the largest power of two that fits in the original (largest
available hunk) size returned by the Malloc(-1L).

Like I said, you just have to cross your eyes right to visualize what's
going on.

> Questions:

> a) Is the "Malloc" call at (1) getting the largest available block in
> the operating-system-maintained free list?

Answer: it is returning the _size_ of the largest available block, not a
pointer to such a block.

[I _hate_ it when a call can return values in type conflict depending on
the parameters; miserable software engineering design; it should be two
separately named routines returning the pointer versus the long integer
values, even though pointers happen to be implemented _on_ _this_
machine as long integers.]

> b) If not, what's going on with the "-1" parameter (and is it being
> promoted to a long integer behind the scenes, while I'm asking)?

Answer: it not exactly being "promoted" because the Lattice compiler is
using 32 bit integers as the native default; by me (and by my
correspondent) that makes the "1" a portability problem and thus a
coding error; it should have been "1L".

c) Could the call at (1) return a value _larger_ than "_mneed" is set?

Answer: yes indeed, it will return the size of the largest free block,
which makes the call a system killer on a virtual memory system (and
pretty unfriendly on _any_ multitasking system); on a Unix box this
is typically going to grab 8 megs of memory from the virtual memory
swap area; _way_ overkill when the setting for _mneed indicates that
30K would do fine. Another portability problem.

> d) I'm used to seeing (lower case) "malloc" return a zero (== null
> pointer) when allocation of the requested size isn't possible. Why is
> the test of the value returned by "Malloc" at (3) done against a
> pointer cast of "-1" at (4) instead?

> e) What would a zero return have implied that a "-1" return doesn't
> from "Malloc"?

> f) What exactly is the "-1" return telling me about an allocation
> failure?

Answer (to d, e, and f): it's a coding bug and should have tested
against "0L" or null; like "malloc", "Malloc" gives back a null, not a
(char *)(-1), on allocation failure.

[This still is a design problem with "Malloc", though, because "zero"
(there are no free blocks) is a legitimate, non-failure answer to
"Malloc(-1L)", though in practice there isn't much difference in what
you'd do in response to "no storage free" versus "attempting to get
storage failed" in any case, but the response should _not_ confound the
two answers; more bad software engineering.]

> Email responses only, please; I really try to keep out of newsgroups
> where I have no business, since I tend to answer 10% of what I read
> otherwise.

I'll go away again now.

;-)

> If this is something everyone but me reading this doesn't already
> understand, email a request for a summary of responses, and I'll
> gladly post one back here.

Well, no one asked, but the responses were useful enough I thought I'd
post one anyway, since there were some good lessons to be learned.

Thanks again for all the help.

>If I'm wrong here, Allan Pratt
>will certainly correct me in an instant 8-)

Did I hear my name being called?

Ptermres(0,0) is unsafe. Your TPA is shrunk to zero size (or freed) before the terminate happens, and therefore you are relying on the contents of memory that nobody owns: the contents of your basepage to process the terminate. This is bad news. Don't do it. The minimum size argument to Ptermres should be $80 (the size of your basepage, up to the command line). This wierd case is not one the authors of GEMDOS (including me) anticipated, so it's not enforced or anything. I guess it could be.

Of course, people frequently *do* rely on the contents of memory that nobody owns, but it's not SAFE. In particular, that address may have no meaning any more in a VM system.

If you're referring to the posts to .tech and .atari.st from Fidonet
gatewayed by egsgate, I've already complained about it, in mail (no
answer) and in news.admin (for which I got flamed).

Somebody running a gateway using FredMail software has a configuration
problem, which I can understand, and an inability to respond to mail,
which I cannot.

It is my belief that the badly formatted messages have hosed up some
Usenet news batches at intermediate sites, causing other messages from
innocent parties to be lost.

I was informed by my rude public correspondent in news.admin that the
problem was fixed the same day it occurred, but it continues to manifest
itself. It must be both of our imaginations, engaged in an anti-Fidonet
conspiracy. :-)

1932. Re: GIF to SPC convertors

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-12 01:17:32 UTC
From: rosenkra@convex.com
Message-ID: <1991Apr12.011732.8868@convex.com>
Source record: 48510

i posted src to mgif on c.s.a.st which includes the tricky .GIF decoding.
i end up with rgb buffers for each scan line. after that, you can do anything
u want, including recode for .SPC and dump to disk. the .spc format is
documented in the picfmt files also on atari.archive (forgot the author -
sorry). what i did was run the rgb arrays thru a floyd-steinberg ditherer
so i could view the image on monochrome (hence m(mono)gif). since i use my
sc1224 about once a year, i prefer mono gifs. as far as i know, this is
the only generally available gif viewer for which src is available. i lifted
the gif decoder from PBMplus, also on atari.archive, though no src (i used
comp.sources.unix sources). the f-s dither is my own doing. if you can get
the decoder to run faster, i'd appreciate a copy...

now that i think of it, i think the PBM package includes giftopbm and pbmtospc
converters. i have not tried these, however. with a shell that can pipe,
you should be able to do:

giftopbm file.gif | pbmtospc >file.spc

or maybe

cat file.gif | giftopbm | pbmtospc >file.spc

pbm format is a generic (portable) bitmap format. maybe you need ppm (pixmap)
for color images (giftoppm and ppmtospc). read the docs on PBMplus. i don't
remember which is which...

>own executable.

Why not:
1. Try ARGV/xARG
2. Try shell_read
3. Fail

shell_read will work for Desktop run stuff.
ARGV/xARG will work for stuff called from command line.
If the user tries to use the program some other way (?) then that is
there hard luck. Personally, I'd rather not put data into my executables
anyway (what's wrong with separate files and environment variables? Much
more flexible - we lose more flexibility in embedding data than we do by
failing if the user calls our program by an obscure means.)

1935. My SM124 (ST monochrome monitor) died, like so many have lately

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-12 07:06:52 UTC
From: mspacek@fquest.fidonet.org
Message-ID: <6040Z2w164w@fquest.fidonet.org>
Source record: 48526

Well, I've seen a thread of messages about monochrome monitor problems lately, but pretty much ignored it. After all, it could never happen to me! Right, well it did happen to me. The other night it had been on for a while... I was online with a BBS and all of a sudden I thought the characters were starting to look funny, like they were slanting just a bit and getting thinner. Well, just a moment or two later the screen went dark and the green power light were dark also. When I turned the system off I could still hear a humming from the monitor, the power supply I suppose. I then cut it off to be safe. I opened it up and checked the fuse. It was blown. I really didn't expect it to be that simple, but thought it was worth a shot. I went to Radio Shack and bought a couple new fuses of the same rating. I thought I might have gotten lucky because it seemed to work fine after I replaced the fuse and put it back together. But after a little more than 30 minutes elapsed, it happened again. This time I was looking at the right side of the screen when it occured and the letter were definitely getting VERY thin right before it happened. Once again, it was only a moment or two after I noticed the character distortion until it went out. Anyway, I'm hoping to get some help in diagnosing the problem since there isn't much in the way of local dealer support. Oh, I thought both times that the monitor felt hotter than it should have right after the fuse blew. I would also welcome advice on what I could do if I can't fix it. Like good places to send stuff like that to be repaired (if there is such a place, not around here anyway), or what Atari Corp's exchange program pricing is currently. If anyway has had a posted for help with a similar sounding problem, I would sure love to hear what happened to them and possibly a recap of the help they got. I guess mail it would be best to mail anything to me, unless you think others would find the info interesting or helpful. I know I should have been reading the posts that have been on here lately and may well have already known the problem if I had, but well, I didn't. So, any help will be greatly appreciated. I really like my mono monitor and miss it greatly. I'm quite used to it and want it back pretty bad. SOMEBODY HEP ME PLEASE!!! Heh...
Thanks in advance from a SM124 addict suffering from withdrawal symptoms.

Hello again.

I post the orginal message. My thanks to all that replied. It turns out that the viewer was at fault.

No where in the Documention does it say that SPLINDEX.PRG requires the monitor to be running in 60hz mode (and not 50hz as in the UK for most monitors).

This has been solved.

Next question as a result: Does anyone have the source code (in Assembler if possible) of how to swap between 50hz and 60hz, as I would like to include it in a program.

Dave

From: glens@natinst.com
Message-ID: <21841@natinst.natinst.com>
Source record: 48515

Hey does anybody know a company which makes a 13 pin circular din to plug into the ST/STE monitor Port or a place I can get my hands on one. (working on my own ST->Multisync and possibly GenLock device sometime in the future).

Thanks in advance,
Glen

>converters. i have not tried these, however. with a shell that can pipe,
>you should be able to do:
>
> giftopbm file.gif | pbmtospc >file.spc

That would be:

giftoppm file.gif | ppmtospu >file.spu

If the GIF was not 320x200, you'd have to do:

giftoppm file.gif | ppmscale -width 320 -height 200 | ppmtospu >file.spu

Ppmtospu uses the same algorithm to convert to Spectrum that GIFSPC uses. However, since ppmscale uses a much better algorithm to scale a picture that is not 320x200, large GIFs would probably look much better using PBMplus instead of GIFSPC. Ppmtospu also has a 4x4 dithering option which GIFSPC does not have.

BTW, if anyone wants to build a better GIF to Spectrum convertor, the sources to giftoppm and ppmtospu would be a great place to start. I still have most of the source to GIFSPC, but it is very poorly written, and slower, compared to giftoppm, ppmscale, and ppmtospu.

1941. Edicta Expansion board problem...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-12 15:44:20 UTC
From: hb9zz@bernina.ethz.ch
Message-ID: <1991Apr12.154420.25785@bernina.ethz.ch>
Source record: 48547

Hi everybody,
I've installed an Edicta 2 Mb expansion board on my atari st, but I'm
getting a lot of problems. My Computer is a Mega ST 1 with the "bad"
GLUE chip, but changing it with another of an old 520 ST (a good one, not an IMC or what
the name is)
does not change anything... I continue to get bombs the time the HD
driver is loaded...
Does somebody have the same problem? any sudgestion?

Thanks a lot in advance

Ciao --- Rick

>Ptermres should be $80 (the size of your basepage, up to the command line).
>This wierd case is not one the authors of GEMDOS (including me)
>anticipated, so it's not enforced or anything. I guess it could be.

This is what I expected. The discussion, however, was on the question
where malloc'ed blocks go to when you do a Ptermres(0, 0).
To my knowledge, the malloc'ed blocks vanish from both internal
memory lists and so stay resident. I don't see how code packed into
those blocks can crash if it doesn't rely on still being a process
of its own.

Having borrowed your ear 8-), I add a new question: How can one
test reliably if some GEMDOS drive is a BIOS controlled device
or a MetaDOS device?

1945. Re: How store extra data at the end of an executable?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-12 21:09:38 UTC
From: apratt@atari.UUCP
Message-ID: <2904@atari.UUCP>
Source record: 48527

>erik@mcrware.UUCP (Erik Johnson) writes:

>Here is what I would like to do. I would like to append a picture file to the
>end of my executable file. In this case, the extra data is a picture file that
>is the menu for my program. Once a program is loaded into memory, is it closed
>and all file offset information lost, or is there a way I can start reading
>data from the file where the program data left off.

wolfram@ikki.informatik.rwth-aachen.de (Wolfram Roesler) writes [some stuff
based on wierd and wrong guesses about how things work].

You can't just tack the picture data onto the program file after the
program's data segment, because that would mess up the BSS segment.

I reiterate: you should not try to "append a picture file to the end of
[your] executable file" but rather "arrange for a picture file to
be included in your program file." This you can do, in the worst case,
by turning the picture file into an assembly (or C!) source file,
assembling (or compiling) it, and linking with the resulting .o file.

Example using my DB (it doesn't matter what compiler you ultimately use):

```
:read picture.neo
:transcript mypic.c
:dw(+ `rwstart 4)[@32] ; dw(+ `rwstart 80)[@32000]
:transcript off
```

Now, in mypic.c, there's a top line you should delete ("dw..."), two lines'
worth of palette data, and 2000 lines' worth of picture data, followed by
another line you should delete ("transcript off"). You have to edit the
file to remove the address and ASCII fields from the dump, and prefix each
number by "0x", and put commas between them, and now you can wrap them in
to C as array initializers, so the result looks like this:

```
short paldata[] = {
0x0777,0x0007,0x0070,0x0700, ...,
...
};

short picdata[] = {
0x ...
};
```

and now you can compile this file, link with it, and use the symbols
paldata and picdata in your program.

>errors: the structure DMABUFFER is expected in stat.h, the Sozobon stat.h
>doesn't reference it, and "aesbind.h" is expected, which also isn't in the
>Sozobon or dlibs distribution. Any ideas how these can be compensated for
>or where I might find AES bindings (are they in another .h file?)

This Emacs for the ST is GREAT, but the portability stuff is TERRIBLE. If you're on an ST, the code only works for ST520 and ATARI and MWC. If you want to do something different, like a different compiler, you're in for trouble.

Basically, you should leave MWC and ATARI and ST520 defined and then and remove code as necessary for your compiler. DMABUFFER is the MWC name for the DTA structure; it's only used in getffile and getnfile. Substitute the DTA struct from your compiler (check osbind.h or make your own) and fix the field names in the defines that have "info" in them.

As for aesbind.h, it might be called gem.h or gembind.h. It has the AES structure and constant definitions, the companion to vdibind.h.

[about inserting scancodes into the keyboard buffer]

>OK, but does this also apply to evnt_keybd and evnt_multi ?

There is an interrupt vector that resolves into the various handlers for MIDI, keyboard, etc. However, I think it is the actual keyboard handler that flags the keyboard events. Therefore, you are also looking for a legal way of flagging the events.

>And what about the keyclick, the ikbdsys handles that. Fact ?

Yes, the keyboard click is triggered there. If you want to generate a real keyclick, you also need a hook into the system keyclick.

1948. UNIX on an ST?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-13 11:52:08 UTC
From: fred@fredw
Message-ID: <0426455@fredw>
Source record: 48576

I recently overheard someone comment on an Atari Unix system being offered in Europe.

CAN IT BE TRUE? :->

I understand that Amiga now has a unix system, so the prospect of unix on the ST sounds mighty encouraging; especially to those of us who love their ST and love to boast of its capabilities. However, if Atari doesn't get on the unix bandwagon, I'm afraid that there won't be much for us to boast of.

When I often suggest Atari to someone entering the home computer world, their first question is often, "what about Unix?" At which point I have to lower my head and submit that I really don't know. :-(

Anyway, back to the point of all of this. Can anyone out there tell me if that comment was true (or untrue) and/or provide me with any other information on the subject?

Hopeful

I have a buddy who just got a TT. He wishes to connect his 80mb Supra to the machine (which already has a HD), thus having access to both drives. He did this by plugging the Supra into the DMA socket on the back of the machine. The internal hard disk uses the Atari HD software, and is at SCSI 0 (thus is the boot drive). His Supra is set at SCSI 1.

Problem: The machine sees the Supra, it parks it when park.prg is run, and it can reformat it, but the desktop cannot see the partitions. He tries to install icons for the partitions, and cannot do so.

Does anyone know of something obvious he could be doing wrong (dealing specifically with the TT and the Atari Software)? I have never worked with the Atari HD software, are there any quirks he/I should know about?

Thanks in advance.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-13 19:56:39 UTC
From: scale@abode.wciu.edu
Message-ID: <1991Apr13.195639.4821@abode.wciu.edu>
Source record: 48535

Hi Kelly,
Upgrades will typically cost from $250 (for 2m) to $400 (for
4m) with usually either a JRI (uses SIMM's) or a Zubair (uses DRAM's) upgrade
board; these prices may or may not include installation. Also if you want to
upgrade to TOS 1.4 at the same time (a very good idea), that would be around
another $100 for TOS 1.4. Sounds expensive, doesn't it?!
Well on the other hand you could buy a brand new 2m 1040STe with TOS
1.6x for $500 (or a 4m 1040STe for $600!); then sell your older 1040ST for
around $200. Price wise, you end up spending about the same amount of money
buying a new machine as you do upgrading your old machine; the difference
being, you end up with a better machine.
I hope that I helped at least a little, bye.....

1953. Getting Started w/ a Hard Drive (HELP)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-13 20:55:53 UTC
From: reyy@vax5.cit.cornell.edu
Message-ID: <1991Apr13.165553.4024@vax5.cit.cornell.edu>
Source record: 48534

Greetings,
I recently borrowed a hard drive from a friend of mine and
I can't seem to get it to work. But then again, I've never tried
to hook up a hard drive before. The problem I'm getting is that
the computer won't recognize the fact that the HD is there. I tried
HINSTALL.PRG but it tells me there is no logical drive available;
either that or it gives me two bombs. (I got HINSTALL.PRG from HDX301.LZH,
from atari.archive). Anyway, anyone want to give me a crash course
on how to set up a hard drive? (Also, the HD may have crashed, so I
might need to reformat, but I tried and it won't even let me do that;
but I'd rather try to see if I can try to get it running first).

Here's my system (Don't Laugh!)
Atari 520ST TOS 1.00
1 DSDD drive
1 SSDD drive
Color Monitor
and the drive is:
SupraDrive 20MB with a Seagate ST157N (not sure, the 48MB Seagate)
replacing the original drive.

Please respond via e-mail.
Thanks for all your help!!!

The March 1991 issue of ST Informer describes how to connect a 1.2 gigabyte Micropolis Model 1598-15 hard drive to an ST. Make sure your host adapter and driver will work with whatever drive you have.

In any case, regarding TOS, the article says, "I knew that the I wanted the first partition to be 16 megabytes. That's the largest that a boot partition can be on a TOS 1.0 system like mine. Boot partitions on systems with TOS 1.4 and later versions can have 32-megabyte partitions.

"For the remaining disk capacity, I elected to be symmetric and specified four maximum-sized (256-magabyte) BGM partitions."

BTW, he was using ICD's utilities with ICD host adapter.

I usually load the program into a sector editor and change the drive
indicators by hand, looking for "A:\" or something similar and changing it
to "C:\". Some programs won't let you do this. What program are you trying
to change?

If there is a program out there that does this automatically, I would
like to know about it too. :^)

I changed the "A:" in tapemakr.prg (make cassette sleeves) to ".\" to get the
current directory. This works well for me, since the data files are in the
same directory as the program.

I wrote such a program a few weeks ago. I'll do some last testing, write the documentaion, then I'll post it to comp.binaries.atari.st.

The program works as accessory, which allows you to choose any folder on your harddisk as logical drive 'A' or 'B'.
One advantage: You really may choose any folder, so you wont have to use C:\ for all these programs who never heard of hard disks.
One drawback: It is dangerous to change the drive within another program, which could have open files on the specified drive. (Just as this program wont like it, if you plug off a physical drive.)

It would be even better to remove the leading "\", thereby allowing
you to just dump the stuff in a subdirectory, instead of cluttering up
the root of some partition (which I like to keep small).

1964. ghostscript, dvips on ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-15 21:24:45 UTC
From: timothyg@ncsa.uiuc.edu
Message-ID: <1991Apr15.212445.18348@ux1.cso.uiuc.edu>
Source record: 48553

Hi,

This is my third attempt to post this info. I'll get it right
one day.

I have a partial port of ghostscript (GNU project's postscript
interpreter) running on the ST. I know of one small bug, but as
soon as I get gdb working, I hope to exterminate it. I currently
have only the HP DeskJet driver working, but I think (hope) it
will be simple to install any of the other drivers distributed
with ghostscript (i.e. epson).

I am soliciting any information (about the atari and ghostscript)
which might help me to write a screen driver for the ST. I am not
very familiar with ST hardware, TOS, GEM, or the ghostscript
device interface, so that is a tall order. Perhaps someone will
volunteer to write it for me (wishful thinking). Is it possible
to have a GEM screen driver for a non-GEM program? Can I hack
one of the MSDOS VGA drivers?

I also have dvips running on the ST. Dvips converts TeX .dvi files
to postscript files. It supports the use of TeX 'special' commands
to include postscript graphics in TeX/LaTeX documents. The
TeX/dvips/ghostscript combination can be very powerful.

I can post these programs (as they are) if anyone is interested and
is willing to give me instructions for how to post executables.
Thanks,

Tim Gallivan

From: tony@tacky.cs.olemiss.edu
Message-ID: <1991Apr16.063556.1204@cs.olemiss.edu>
Source record: 48555

Until yesterday, everything was fine. I'm running HDX 3.01, and TOS 1.4
on a 1040ST with 1MB. My HD is a SH204. I have a single 20MB partition.
It has been up to 17-18MB full, and I recently pulled stuff off to make
room for MiNT and MGR. Fine. Now I start to fill it up, and WHAM!
It reports that I've only got 15MB! Reboots, turn-off, cable-shakes,
you name it. Still, 15MB! I want my hard drive!

My only access to new software is through the Internet. There's not
another ST around for miles. Hundreds of miles. We're talking
PC boon-docks.

Ideas?

This may give me the perfect opportunity: reformat with a 15MB
TOS partition and a 6MB MINIX partition for use with MiNT. I
need *mkfs* for MINIX. Does the mkfs that comes with the demo
of MINIX work on the Hard Drive? How about the address of the
ftp site where the MINIX demo hides if it does.

Thanks a million.

My friend managed to get his external Supra HD connected to his TT (which has an internal SCSI device). The TT differentiates between SCSI and ASCI devices. The internal drive is set at SCSI 0, so my friend set his Supra at SCSI 1, so they would not confict. This turned out to be the problem. BOTH drives had to be set to SCSI 0 to work. Extremely weird. Anyone have an explination?

The canonical version of Mtools is indeed posted at the .mil site mentioned in recent postings, but when I tried to FTP it (it is a 4-part set) one of the parts absolutely refused to transfer completely. It invariably truncated every time I copied it. I finally got a good copy at inria.inria.fr. The version I located is v2.0, and has support for CD, FORMAT, LABEL, and ATTRIB, plus a mkmanifest tool to assist in restoring unix file names that get lost in the translation to DOS file names.

Hmm ... I doubt this will work. What I did some years ago was to put an ST mouse into a C 64. I wrote a simple driver program for it (<200 bytes 6502 code :-), it really worked!! It was the best mouse at all (much better than all these pseudo-joystick mouses I'd seen before), but unfortunately no commercial program was compatible to it. So only my own programs supported this little hack.

What did he plug the Supra into, daisy chained off the SCSI port, or
the Atari DMA port? If DMA port, then the answer is that you're using two
separate buses...

Being a poor, VERY poor type of person, attending a HALF BAKED comp sci program and paying a PREMIUM price for it...

I decided to strike out on my own and investigate the many exciting possibilities of dicing aprt gcc and figuring out how the thing works.

Turbo C's Turbo Debugger is particularly good at doing stuff like this.

So could someone please tell Gregory where all the source is for the TOS version of gnu stuff? Perhaps a fiel list to get would be nice?

ftp 141.211.164.8 is where I have access.

Thank You much...

I just want to tell everyone that I tried for the first time ever to
connect a hard drive to my ST and it's the easiest thing in the world.

I used the ICD AdSCSI adapter in a D&P enclosure and a Quantum drive, and
had it formatted, partitioned and running in under 2 hours. I have
TOS 1.0.

Total cost to me was $375 with a 40-MB drive. I wish I'd done this years ago.

So if you have ever wanted a hard drive but can't afford one and are
afraid to build you own, don't be. :-)

Greetings,

I've just received a SupraDrive Hard Disk from a friend,
but I can't seem to get it working on my ST. I'm very
new at hard drives, so everything I've done is experimental.
About all I've been able to do is test the access speed with
HDCHCK13.TOS!

I think my problem is that I need a copy of the utilities
that go with the hard drive (i.e. Supra's utilities). But
neither my friend nor I have them. (is this assumption
correct? i.e., I can't use non-Supra utilities on a Supra
drive? I tried HDX and no-go.)

So, that means I need a copy of these utilities. Is there any
reason why someone can't mail them to me? (I've got the drive,
it should be legal to have the utilities, too!) If not, does
anyone have a copy they can send me??? Please???

FYI, my setup is (and don't laugh):
Atari 520ST
TOS1.0
1 DSDD drive, 1 SSDD drive
SC1224 Monitor
20 MB SupraDrive, upgraded to 50 MB (w/ a Seagate ST157N I believe)

Thanks,

He plugged it into the DMA. However, if it is a separate bus, then it
was the only device on it. So why does the Atari software demand that
it be device 0? That is what puzzles me.

Do many people have the ICD AdSpeed?

I recently put one in a Mega ST-4 with a Moniterm board and
it seemed to work pretty well. I left the machine on overnight
and it had crashed by morning. It seems that it crashed within
a few hours. The problem seems to be heat related, because the
system seems to get flakey after it's been on for a while.

Has anybody else experienced similar problems?

>Example using my DB (it doesn't matter what compiler you ultimately use):
> (DB example deleted)

I use Allan's linker (ALN) instead:

aln -p -i picture.neo _titlpic -o titlepic.o

This produces an object file, titlepic.o, that contains the NEOchrome
picture at label _titlepic which can then be accessed as a structure.
I should add of course that the picture will not be on a 256 byte
boundary and so you can't just point the hardware at it (unless you have
an STE or a TT of course).

How about
printf("\x1BE");
or maybe
Bconout(2, '\x1b');
Bconout(2, 'E');
which essentially is the same. This is for TOS applications.

> Marcus Bointon.
>

After having never seen this for 5 years, I finally had it too.
I was just typing in First Word Plus (not even fast typing).

Besides the symptom described by Marcus above, I also had the following:
The last two charcters typed in, repeated only once, and from then on,
the ST takes ages (ok, just about 5 seconds I guess), to draw every
next character on the screen. I am able to select the save option in
the menu (which popped up rather fast-), but the actual save action
never starts. Only Ctrl-Del-Shift-etc helps.

For your knowledge:
No programs were started within the autofolder, and
I had only the SNAPSHOT accesoire started.

Is this the always denied PHANTOM TYPIST?

Stop filling my mail queue, please! I surrender! 8-)

I will write a short doc for the program and place it in the PD.
In the meantime, maybe someone could explain me how to make sure
that it appears in comp.binaries.atari.st. I tried the recommended
path once with some other program, but never succeeded.

The UManitoba ether mailer has no idea where you are, so ...

Do you want to clear the screen or black it? Two different things. If the
latter, try saving the palette and resetting it to zeroes.

int oldpal[16], i;
int pal[] = {0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0};

for (i=0;i<16;i++)
oldpal[i] = Setcolor(i,-1); /* save old palette */
Setpalette(p); /* set new palette */

...

Setpalette(oldpal); /* restore original palette */

Note: This is off-top-of-head, untested code. Corrections welcome.
I have no idea how an STE or TT would react to this code.

Yes, but why does this explain why it will not work with an id other
than 0? I can see that if TT SCSI and ASCI are seperate buses then it is
ok to use the same id. Does this meen that the TT ASCI port only
supports one device not the full 8 on the ST. If it supports the full 8
then with two buses or 16 SCSI devices the TT can handle some serious
backing storage :->

The driver is called CBHD and is part of my book on harddisks
published by MAXON. The upgrade is easy and is described in
the book. In short:
- use a 3.5" drive (5.25" drives won't fit)
- use the second 20 pin connector on the controller board for the
ST506 data bus; the control bus is shared
- remove one of the two terminator packs
- make a small modification on the controller board (phone or email
me for details)
- get software that knows how to access the second drive (for example,
see above)

How about using the `clear screen' VT52 escape. Can't think of it off-hand, but you should be able to find it documented somewhere. Or else some other netter with a better memory than mine (not difficult :-)) might help you... (The good point about this method is that it takes virtually no programming: just a printf statement.)

From: ytsuji@wucc.waseda.ac.jp
Message-ID: <5479@wucc.waseda.ac.jp>
Source record: 48582

As to connecting two sets of bus lines:
1) I simply bought these flat cables from a shop (adding the second drive to ADAPTEC board is a common practice in IBM PC world).
2) One or two of the 20-pin data bus had been disabled and had to be cut and enabled.
3) finding suitable a mounting kit and additional power supply required some inventiveness but I managed.
4) Minix-ST presupposes the existence of unit 0 lun 1 and ICD's TOS driver just works fine. Sorry, I haven't even tried to use the driver that came with my Megafile.
Hope to have been of some help.

Yeah. At CeBIT, Atari showed Unix System V running on the TT030 with
X.Windows a graphical user interface called Wish.

But it won't run on the ST.

> When I often suggest Atari to someone entering the home computer world, their
> first question is often, "what about Unix?" At which point I have to lower my
> head and submit that I really don't know. :-(

You can tell them about the TT, and you also can tell them about Minix, which
is based on the specifications for Unix Version 7. (That's not a later version
than System V -- v7 is more like System III.7.) It costs about $140 and is
available from Prentice-Hall. See comp.os.minix.

There was another Unix clone called Idris developed by Whitesmiths
a couple of years ago, but it wasn't marketed properly (i.e., it wasn't
available in stores at a reasonable price) and I think it's dead now.
Mark Williams may also have worked on an ST version of Coherent, but
so far as I know, it was never released.

What is M-Tools, exactly? I haven't heard of it before, so I'm curious.
It it a HD Utility, or is it some form of CLI? Thanks for the
information (I hope).

Moreover, there's a demo of Minix at an ftp site, and I'm sorry I can't
remember where. Perhaps it should be posted at atari.archive. If anyone
wants it there (if it's not there already), let me know.

1997. RE:RE Megafile 60 extended by ad. drive

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-18 10:04:25 UTC
From: ralph@prosun.first.gmd.de
Message-ID: <608@bigfoot.first.gmd.de>
Source record: 48584

Hello Claus, thanks for your answer.

Ok, I've readed your answer and yesterday I've readed the Scheibenkleister II book in detail the part of the CBHD driver and the SCSI-ASCI.

[1]
Perhaps you can mail hits for the small modification on the controler board.
What's about overpowering the power station as described in Scheibenkleister?

[2]
In addition I do'nt understand (after installing the CBHD Driver) how you can address the second Drive on the same ASCI port. Can TOS manage this feature.
So do you have a drive as [C:0] and [C:1] on the desktop as Icons or else.

[3]
I've also installed the CBHD driver on my C-Boot-Partition-0.
Because I did'nt what to format my disc, I've just installed the CBHD driver with the INSTALL command of the SED, including using the default SEDROOT.DAT SEDBOOT.DAT resources. Ok it works. But on booting the ST from the Boot-Partition, the drivers says Bootblock modified VPL vectors modified, might include a virus. What can I do?
Is it possible to read the old ROOT-Sector(I've saved it onto the Floppy) by the SED to get the information for the Installation?

[4]
I've installed the Luftschloss(V2.6) RamDisc. Running well within TOS 1.4.
Second I've installed the Neodesk3(3.01). Now I've got problems.
Also starting the RamDisk at first in the Auto Dir (so belonging to TOS and not to Neodesk) isn't save. Every time opening the RamDisk Dir the TOS(or?) generates an ERROR Dialog reading "Daten defekt? Pruefen Sie die Verbindungs-kabel oder legen Sie eine Floppy ein. TOS Fehler [-1]".
What's wrong? Might be Neodesk3.
Do you have any experience with this?

Ok, I think it's more than enough, but on (things.take.time) I thank you in front

I use Minix on a Mega 2. It's quite a nice package, but it's not even close to Xenix much less Unix. Minix is still really a hacker's toy, not a complete OS, and you have to be prepared to spend a lot of time on the net reading comp.os.minix and downloading patches, etc. (This will change a bit when Advanced Minix is available for the ST).

The reason (or one of the reasons) that we don't have Unix on the ST is that the 68000 is not really able to run it, because it has no memory management. The 68020 or 68030 is quite capable, though. If you REALLY want Unix with X-Windows, etc., here is what you will need:

1) Preferable at least 4 Megs RAM.
2) ca. 100 Megs HD space, JUST FOR THE OS
3) 100-200 Megs HD space if you want a full news feed
4) 25-50 Megs swap space for virtual memory.
5) Whatever you want for your own programs (you'll need 5-10 Megs just for emacs, for instance).

At the Dictionary of Old English, we have three regular programmers using Unix with 1 Gigabyte of Hard Disk space, and we are so tight for storage that we lost a chunk of incoming news last weekend, and we are constantly moving stuff to tape (oh yeah, you'll want some kind of tape drive...).

I personally would love to have Unix at home, but we should carefully consider the implications first. You could probably get away with a really stripped-down unix on 100 Megs, but forget about getting a news feed, having more than one user, or porting any programs (you'll have about 10 Megs free, depending on the setup). Also, forget about big packages like X-Windows, emacs and TeX, much less Posix conformance. The Unix that you would end up with is not the Unix that you use and love at work.

1999. MWC & hiding objects in resources

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-18 11:27:00 UTC
From: sean@ccwf.cc.utexas.edu
Message-ID: <47391@ut-emx.uucp>
Source record: 48586

I'm having trouble hiding objects within a resourcce. I've tried changing the object's flag (i.e. obj.ob_flag = HIDETREE) and redrawing the tree - but no go. I can do anything else (make selectable, crossed, deselected, etc...) but I can't hide the object.

I'm sure this is possible (the Resource Construction Kit allows it). Also, when I decompile a resource containing both hidden and unhidden objects (using the resdecomp) the listing states those objects that were hidden with the entry "OPTION: hidden". And when I execute the resource, sure enough, the objects with "OPTION: hidden" are hidden and those without are displayed.

Any suggestions?

Thanks,
Sean Sterling Foiles / Univ. Texas Comp Sci Grad / sean@happy.cc.utexas.edu

I believe that the HIDETREE flag should be set for the *parent* of the object
you wish to hide.

I have been eyeballing the color printer that is being sold by Tandy.
I am wondering if anyone has ever hooked one up for use on their ST and what kind of results they had. I am looking for something to do some color printing as well as doing some rough drafts of my DTP work before taking it down to the school to laser print.

If anyone has any experience with these, I would appreciate it.
Especially with postscript files.

2006. Ste fix for 2.5 meg upgrade?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-18 22:23:03 UTC
From: pdel@ADS.COM
Message-ID: <-P6&-`$@ads.com>
Source record: 48588

I just upgraded my STe to 2.5 megs like it says to do in the March '91
issue of Atari interface.
I put the 1 meg simms in slots 1 & 3 (from back to front) and the other
2 256k'ers in slots 2 & 4.
However, a memory checker says I have 4 meg. they said this would happen,
so go get a program called simmfix.arc that's s'posed to fix this.

Well, I looked on compuserve and Delphi and didn't find anything. I also
looked on atari.archive but don't know if the file is called something
else.

Anyone have any clues or fixes for this?

thanks, Peter D.

yes, but beware of race conditions! or in other words, disabling
interrupts while doing these things sounds like a veeery good idea...
(reminds me of that `phantom typist' thing - is it fixed now? well at
least you're _not_ the first one who, while dealing with interrupts,
didn't think of murphy's law 25 hours a day. :-)

BGM stands for Big GeM; at least that what one reference called it. I think
can only be used with TOS 1.4. It sets the sectors (correct term?) to anything
higher than 512 bytes. You can go up to 2048 I believe.

I tried SIMMFIX a few months ago, and it worked fine, when it did. The
program is 248 BYTES long, and the computer wouldn't always recognize it
as a program. I would sometimes get a TOS Error #35.

The solution to this problem is to either go with two megs or go with four.
BTW, SIMM prices seem to be on the rise. I bought two 1megx8 80ns in Jan
for around $85. I bought two more this past week for around $97.

No experience with a Radio Shack printer, BUT... I've got a Fijitsu DX-2100 color printer that I never use anymore since I've sold the rest of my system. I paid $500 for it about 3 years ago, And I'd like to get about $225 or so for it now. It's a real workhorse and it's Epson JC-80 compatible which makes it work with any software. I had excellent results with it on my ST. Fujitsu is a really big company. They still make a similiar model which uses the same ribbons. Most of their products are used in industry, so you don't see a lot of them anywhere else. If you're interested, let me know...

Hey, I have no experience with a Radio Schlack [sic] color printer, but I do have a Fujitsu DX-2100 Color printer that I don't use anymore. Fujitsu's are big in industry and business, and the company makes just about everything you can thing of for computers - they're here to stay... The model that I have is about 3 years old, and has been replaced with another version that uses the same ribbons, so there is no problem getting them. I have no use for the thing since I've sold my ST and have no computer. It is Epson compatible and uses a JC-80 driver so it works with just about any program. I've got some old Tom Hudson driver that will allow dumps from any screen as well. I paid about $500 for it back then, and I'd like to get about $225 for it now. It's really quite a tank of a printer, it has a really pleasing NearLetterQuality mode, and is about 210 cps in draft. Lemme know if you're interested.

It is a set of programs that lets you handle floppies formatted for MS-DOS
(or Atari) on your Unix machine.

I have it installed on my Sun IPC and use it to exchange files with my
Atari ST. The big plus is that it works much faster than transfer over the
serial line.

2018. Phantom typist

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-19 10:58:02 UTC
From: johnj@knor.prl.philips.nl
Message-ID: <2737@prles2.prl.philips.nl>
Source record: 48406

As I stated in a previous message I finally run into the
phantom typist, which I always thought did not exist.

I am using the same machine (ST520 with 1MB) for 5 years,
now and stil using the same version of first word plus.
And I always do a cold reboot before starting First Word plus
(from floppy A) to kill possible virusses (I even wait some
time before switching on again).
That floppy only contains the First Word Plus program, the
First Mail program and only one accesoire (Snapshot). There
is no auto directory on the floppy.

The only difference in those years is the upgrade from TOS 1.0
to TOS 1.4 a few months ago, and that I use the automatic
program start-up facility that TOS 1.4 offers to start
First Word Plus.

What happens:
- During (even very slow) typing, suddenly the last few characters
(sometimes 2, 3 4 or 5 chars) typed in being repeated automatically
rather slow on the line I was working. If I'm aware of it soon,
I can do a (cold) reboot by the Ctrl-Shift_ALt-DEl key press
that TOS 1.4 offers. But in most times, it results in 9 bombs
on the screen and a hard (=switch) reboot is required.

After having it rather often in the last weeks, I think I found a
cause of the problem. Although I'm not 100% certain, I try to
believe that the symptom always started after typing a character very
fast after pressing the backspace key!!!!

This rang a bell in me!

In first word plus (and probably other texteditors aswell)
all keys are queued, to allow fast typing.
However, the delete and backspace key (as I noted) are not
queued (not visibly anyway). This is done to provide you from
deleting too much characters.

This inconsequent keyhandling mechanism may be the cause of the
problem.

Although the above still does not explain, why I never saw the
phantom typist for all those years I used TOS 1.0, it finally
may give a(nother) start point for some investigation in this
matter.

Any ideas?
Who?

Source record: 48409

Hope this is the right place to post. The upper-level group (atari.st) seemed to be reserved for the fervent discussion of 'demos'.

I am thinking about getting an ST machine. The reasons are 1) wanting to stay away from Intel architecture, 2) the ST runs Minix and 3) these things seem to be unbelievably cheap. I am asking for opinions about the machine, running Minix on it, things you like / dislike, etc. Some particulars:

- I have minix running on the Mac at the moment - how does ST minix compare with Macminix? I would think it would be faster, since mac minix has to run as an application rather than an OS.

- what is the native ST interface like (not minix, but this GEM thingy) compared to the Mac?

- what is the minimum configuration I'll likely be able to get away with? I am eyeing starting out with a 520 - 512k and a monochrome monitor, with some sort of HD. I am used to having 2.5 Meg of RAM and 60 Meg HD on my Mac. It seems like Atari stuff should need less space from what I have heard.

For anyone wanting to ask, 'why not stick with your mac?', i'll just say that the Mac and I have to part for technical reasons! i have thought about getting one of the new macs (the LC, say) but this seems a little dumb when there are these ST's selling for well under $1000, especially the used ones.

Thanks for any email you might send.

Mtools does not run on an ST -- at least it has no reason to. It is a set of utilities to assist cross-developers on non-DOS/non-TOS machines. Originally, it was created to allow someone on a Sun read/write IBM floppy disks. Since TOS is compatible with the IBM format, a Unix-noid can use it to download favorite comp.binaries.atari.st stuff from the network directly to disk. Another possibility is to run the Sozobon compiler on the Unix machine, create binaries for TOS and write them to the floppy disk directly with Mtools. The process avoids Kermit and the other messy serial protocols. The code is easily ported to other hosts, as long as you have some way of reading a 512-byte sector from the raw disk. We have Emmet P. Gray to thank for this; I only use them.
Brian Cooper.

2024. Return codes & how to kill()

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-19 16:45:31 UTC
From: ant@mks.com
Message-ID: <1991Apr19.164531.22350@mks.com>
Source record: 48408

I've been hunting high and low in the DevDocs for information on
how a parent process finds the return code of the child process.
Now I know Pexec() returns a value when it executes a program, but
I only use Pexec() to load, and I initiate the program through
separate means.

Q: What I want to know is the return code passed back in D0, on the
stack, or in some global system location? Is the return code
available at the time of the call to the Terminate Handler?
I'm trying to make mods to the Sozobon Debugger to handle printing
the return values before it exits.

Q: If I've used Pexec() to load a program and I'm handling the
execution of parts of that program. How can I tell the system
to terminate that child process. Basically I want a kill() or
a ptrace(PT_KILL_PID, child, 0, 0) so that I can add a restart
command.

>neither my friend nor I have them. (is this assumption
>correct? i.e., I can't use non-Supra utilities on a Supra
>drive? I tried HDX and no-go.)

You should be able to use any utilities, including HDX. However, you
will have to tell HDX the parameters of the drive (#heads, cylinders,
sectors, etc.) in order to format the drive properly. Since you've
upgraded the drive by replacing the mechanism, even the Supra
utilities might not work for you. They know about the mechanisms that
Supra uses but not necessarily about the one you put in.

Have you tried calling Supra for a copy of the utilities? They might
be willing to send them to you if you can furnish them with a serial
number.

2026. Aerco mem board problem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-19 22:00:59 UTC
From: randyh@hpsad.HP.COM
Message-ID: <18420012@hpsad.HP.COM>
Source record: 48415

I have a problem with an Aerco mem upgrade I recently purchased.

It worked for about a month and then suddenly stopped. My computer would no longer boot with the upgrede attached. If I hook the board up and then remove a single memory chip (any one will do) my computer will boot, but of coarse it only sees 500k of mem. This is also the case if I disconect either of the two ribbon cables from the board.

The memory is good, I checked it out. The other thing I noticed was an awful lot of noise on the +5 and ground lines of the board. This noise is not present on the ST mother board. I changed all the caps and got a little improvement.

If anyone has seen this problem or can suggest some things I could still check, please tell me.

Thanks,
Randy Hosler

2027. Need help with bad RS232 port

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-20 17:04:52 UTC
From: sytang@lamar.ColoState.EDU
Message-ID: <14371@ccncsu.ColoState.EDU>
Source record: 48414

Hello:
My 1040ST has a bad RS232 port and I'm trying to fix it, when nothing connected to the RS232 port it works fine. But when a working modem connected to the port the screen on the mono monitor got distored in some part. And the Uniterm would hung up the whole machine when try to dail out.
(NOTE: Uniterm and modem are working correct and has try with another ST with exact same configuration).
Is it the 1488 or 1489 went bad? OR the Sound chip? Any hints?
Thanks
Tang

2030. Problem with my C program to copy files between floppies

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-21 21:00:56 UTC
From: umochock@ccu.umanitoba.ca
Message-ID: <1991Apr21.210056.5685@ccu.umanitoba.ca>
Source record: 48418

For my first useful C program on my STe, I wrote a program to copy files from one disk to another. I was tired of using a ram disk every time I wanted to copy a file to a different disk (since I have only one disk drive).

I'm using Sozobon C with gulam as my shell.

I try to Malloc a buffer equal to the size of the file being copyied. Then I do a Fread from the source file, prompt the user to swap disks, fopen the destination file, and Fwrite the contents of the buffer. And, fclose both files. Note: I needed to use Malloc, Fread, and Fwrite since I required long ints (not the short expected by malloc, fread, and fwrite).

If I can't Malloc the space I need, I try to Malloc 1/2 as much, and then Fread the first half, Fwrite the first half, Fread the last half (and this is where my problem is), and Fwrite the last half. (I do it in two passes.)

I tested the thing to death and it works under the following situations:

o Copy a file that is smaller than available memory (i.e. only one disk swap needed).

o Copy a file larger than available memory from a ram disk to drive a:. This works with two or even 10 swaps. The swapping is simulated here but does verify that my code to read and write the file in as many pieces as needed works just fine.

It doesn't work when you:

o Copy a file from disk to disk than requires two or more passes. The second Fread on the source file returns 0 bytes read. Checked ferror but it is also zero.

So (and here's my point), I have two files open simulatiously, both in drive a:, but on different disks. And the ST does not seem to like it. Anyone ever try this? Does TOS allow this? Or, is it a bug in my program?

Any help would be appreciated.

You can't just pull a disk out of a drive with an open file on it, UNLESS GEMDOS tells you to. To get GEMDOS to tell you to change disks, change your program to copy files from drive A: to drive B: (yes I know you only have one drive). When your program tries to access drive B: (ie: to open the file) you will get an alert box telling you to put in the other disk into drive A:, when you go back and access drive A: again (ie: to read the second half of the file) then you will get another alert box telling you to change disks again.

This should fix your problem.

>ints (not the short expected by malloc, fread, and fwrite).

Although this isn't what you were asking about, I think it's worth mentioning for the benefit of others who are just starting out:

If you want to allocate more memory than can be specified in an unsigned int, use calloc. It takes two parameters which are multiplied together to get the size of the requested block. To allocate 128K:

```
p = calloc(128, 1024);
```

As a bonus the memory you get is also cleared. You could write your own replacement for Malloc as follows:

```
char *
my_Malloc(size)
register long size;
{
register unsigned hi, lo;

hi = (unsigned) (size >> 16);
lo = (unsigned) (size & 0x0000FFFF);

return calloc(hi, lo);
}
```

(This assumes that a long is 32 bits and an unsigned int is 16, which is not portable, so it's best to use calloc directly.)

In general it is VERY WISE to avoid using the bios Malloc and Free and use the malloc, calloc, and free provided with your compiler of choice. The bios Malloc has bugs (some still remain for historical reasons) and is quite ideosyncratic. Sozobon's malloc and calloc (in dlibs.a) work quite well, although one caveat to Sozobon users is that the malloc routines can only manage 1 Meg of memory. A trivial change to the dlibs source file malloc.c fixes this, fortunately.

Also, assuming you were using fread and fwrite, you would have to be sure to specify "b" in the flags ("b" for "binary") to prevent automatic conversion of CR to CR/LF.

Source record: 48421

In ONE of several similarly designed programs, the name and info lines of windows get crud when another window is topped, e.g. Control Panel. I remember reading something to be careful about with these data, but I'll be damned if I can find it again! I was careful to make both of them static (non-stack) strings. Does anybody remember what to do so this doesn't happen?

If I create a window with WindowCreate(...Closer+InfoLine+Name...), then do WindowSet(...Closer+Name...) and then WindowGet(...WorkXYWH,x,y,w,h), the rectangle that comes back is as though the InfoLine were still there. The picture on the screen, and the behaviour when redrawing or topping verifies this. Is there a way to make the InfoLine temporarily go away, or must one destroy the window and re-create it?

When window B is atop window A, and window B is moved, window A is told to redraw everything of it that shows. How can one repaint just those parts that are newly exposed? It's not too hard when dealing only with windows the program owns, but what about DA windows?

How can one wait for left OR right mouse button with Event<...>? EventButton and EventMultiple wait for left AND right mouse button down if the mask and button arguments are both 3.

Any help, on any question, would be appreciated. To ensure me receiving it, please e-mail answers. Of course, if you think others will be interested, post also.

The Seagate St157N-1 (48Mb, 3.5", SCSI) harddrive of a friend of mine has chosen to display blinking error codes (using the activity LED). We would like to know what they mean. Normally this drive performs a couple of [seeks on startup, but now it either displays 3 or 6 blinks on the LED. The drive keeps spinning.

Any info on this error code is most welcome

>|> deselected, etc...) but I can't hide the object.
>
>I believe that the HIDETREE flag should be set for the *parent* of the object
>you wish to hide.

No. You hide the object by setting the HIDETREE flag bit on the object you
wish to hide, but you must then redraw the parent of the object being hidden.

This actually makes sense, once you think about it. When an object is
hidden, it is ignored by the object drawing routines. If you draw an object,
then set the HIDETREE bit, and redraw it, it gets ignored. This means that
it still appears to be on the display, since there was no visible change.

If you redraw the parent of the object, it replaces the old image. Then, since
the hidden object gets ignored, the portion of the parent which is "behind"
the hidden object continues to be visible on the display.

2036. FATSPEED: great & Reverse execution of AUTO folder programs (?!)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-22 14:24:56 UTC
From: dick@ahds.UUCP
Message-ID: <1970@ahds.UUCP>
Source record: 48426

FATSPEED:
After one year of struggle with defective FAT tables I installed FATSPEED this week in my STF. GREAT!!! (thanks, Graham and Tomas)
Problems I had were verryy sloooow creation of files on my harddisk (btw, a Megafile 44 (the removable disk thing)) and FAT tables in the ST that went corrupt each time I did a 'show info' of a HD partiton, as a result of which some directories showed empty (0 bytes use in 0 items), while they weren't - I had to reboot over-and-over again to repair them.
FATSPEED cured all problems. I vote for an Oscar for it's creator, Ulrich Kuebler !!

AUTO-FOLDER:
I noticed some peculiarities earlier in starting programs from the Auto folder: when I added a program to it never runned automatically at bootup. To get Fatspeed to run, I HAD to get it run at bootup. I also always had the impression that FOLDERXXX.prg never runned (no output, while it generated output - something like 'FOLDER100 installed' when I ran it seperately).

I have tested things as follows:
Newly created AUTO folder, and copied in sequence: AHDI.prg, FOLDER100.prg and then FATSPEED.prg into it. Booted up (cold boot) and looked...
And ONLY output of AHDI appeared in the screen. No output of the other two progs appeared on the screen. FATSPEED did nothing (easy to check) so it never ran.

Next test:
Recreated AUTO folder, and copied the above files now in different order, controlled by instinct. So first FATSPEED, than FOLDER100, than AHDI.
Cold boot, and..... FIRST AHDI runs and generates output on the screen, followed by FATSPEED (displays it's author etc), and at last FOLDER100 runs, producing the Installed message.

??????????????????????????

Can anyone explain this wierd sequence of execution to me ?

Data: Machine = Atari 1040 STF, running TOS 1.2 with attached HD Mega44
---- with AHDI 3.1 diskdriver. No further features installed.

Thanks for any comments on this,

Dick.

If the drive used in your MF60 is a Seagate ST277R, you don't need
the ship program anymore. The ST238R used in the Megafile 30 doesn't
autopark. You can find out the exact type of the drive used by
looking at the back of the Megafile 30 which should bear a label
with 'SEA6065' or something like that if it is a Seagate drive.

You also can use lalloc, which works like the library malloc()
function except that it requires a long argument. (Be sure to include
malloc.h when calling any dynamic memory management functions.)

Also, good advice is worth repeating, so...

> In general it is VERY WISE to avoid using the bios Malloc and Free and
> use the malloc, calloc, and free provided with your compiler of
> choice.

(Possible exception: Desk Accessories.)

Back to the original topic of this thread:

(1) Never remove a disk while a file is open.

(2) Never write a program that tempts a user to do (1).

I'm not quite sure why the original program was written, since the
Desktop handles a virtual B drive nicely (just install it!), but if I
were writing such a program:

(1) I'd be sure to close the files before prompting the user to
remove a disk.

(2) I'd call Mediach() after the swap to force an update of the
GEMdos i/o buffers and make sure the action had been performed
properly.

I might also read the directory to be doubly sure. Beware of Murphy.

A method that works with all GEM versions so far is the following:
Set bit 8 in the evnt_button mclicks parameter. This negates the
event condition in the mclicks, mmask and mstate parameters. To
wait for left OR right button, use the following evnt_button
call:

```
mclicks = 1 | 256;
mmask = 3;
mstate = 0;
evnt_button(mclicks, mmask, mstate);
```

This instructs the AES to come back with a mouse click event when
the two mouse buttons are NOT both released, in other words, when
one of the mouse buttons is pressed.

This method works reliably and is currently being tested at Atari.
I hope they will finally document it and relieve us from mixing
AES and VDI calls to poll the mouse states.

I don't think it's necessarily an error code, but there does seem to be
something wrong with the drive, at least from the information you give us.
Problems with the drives are usually communicated to the user via sense codes.
I don't have any experience with drivers other than ICD's, but it will
usually display a sense code in the upper right hand corner of the screen
if there is anything wrong.

Can you access the drive at all? If so, I'd recommend backing it up if
you haven't done so already.

I'd also recommend calling Seagate and ask them, if no one here has an
answer. Good luck!

Unfortunately, this will not work the way you intend. Assume you want to
Malloc() a block of 65536 bytes. This leads to hi being 1, and lo being
0. This will calloc() a block of 1*0=0 bytes. What you want to do is
factorize size in two factors that are both small enough to be handled
by calloc. I cannot come up right now with an algorithm that does this
both time and memory efficient.
But, there is another possibility. If you are using an ANSI-C compiler,
the standard says that malloc takes an argument of type size_t, but not
that it will be 16 bit. Turbo C, for example, takes a (maybe even
unsigned) long. (unfortunately, this is not the case with MSDOS-TC,
making ports somewhat more difficult)

I have an old 520ST (with only an external floppy drive!) with 1 Mb RAM, and I am having trouble with the serial port. I am trying to use it with a Telebit Trailblazer modem, and it works fine with a low speeds (e.g. 2400 bps) but it tends to lock up at PEP speeds (19.2K bps). I tried installing a program in my AUTO folder which was supposed to fix the problem, but all that did was to cause the modem to _always_ lock up. I've used the modem with other ST's (a STacy and a Mega) and it seemed to work fine, so I believe that the problem must be in my ST. Can anyone suggest anything to check? Is there a likely connection to check, or chip to replace?

Thanks.

2044. Setpallete spelling

Newsgroup: comp.sys.atari.st.tech

From: cliff@jarthur.claremont.edu
Message-ID: <11851@jarthur.Claremont.EDU>
Source record: 48429

Is Setpallete the standard spelling for the sepalette routine? Sozobon C drove me up the wall because it took me some time to find out the function call was mispelled (they spelled it "Setpallete" instead of "Setpalette" which I think be correct). Anyway, I just found that GCC1.39 spells it "Setpallete" as well. What's the deal? My books refer to the call as "Setpalette," and palette is spelled palette. I haven't a clue as to what a pallete is. I went into my osbind.h files and fixed the entries, though maybe I should change it back if others' programs are going to puke on my computer.

What's up?

2045. g++

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-22 23:13:10 UTC
From: cliff@jarthur.claremont.edu
Message-ID: <11852@jarthur.Claremont.EDU>
Source record: 48431

I'm having problems getting my g++ compiler to work. It seems unable to find the standard header files, such as stdio.h. I know, I have to set my path first. Well, I think I have. Here's what's up:

I'm using gulam, and the printenv command says

G++INC=d:\gnu\g++lib\g++-incl

I know that stdio.h is in d:\gnu\g++lib\g++-incl\stdio.h and if I substitute:

#include"d:\gnu\g++lib\g++-incl\stdio.h"

then the compiler works fine.

#include<stdio.h>

gives me errors and says it is unable to find stdio.h. Although this is might unrelated, gcc1.39 has no problems at all.

One more thing. Even if I have #include"d:\gnu\g++lib\g++-incl\stdio.h", the compiler will go through and compile, giving me .o files. It will not link them togethere; it can't find the loader or linker or something (probably the same problem with the paths). I usually then just link with gcc and have no problems. Can someone send me a list of environmental variables that need to be set for the g++ to work correctly?

I'm using a MegaST2 with TOS 1.4.

Any help will greatly be appreciated.

I get sense codes every once in a blue moon, usually right after I tell my friends I never have problems with my HD. I'm using a Seagate 157N, I think. It's a 48.8 meg mechanism with ICD host adaptor and software. What are sense $17 and $15 errors. I think those are the only two I've had. Can I get a listing of sense errors? Who would I write to, ICD, Seagate, or the babooze who I bought the HD from and might have neglected to give me the info?

It was spelled that way in Atari's original osbind.h --- the spelling
has been retained in most compilers for "historical reasons."

>My books refer to the call as
>"Setpalette," and palette is spelled palette. I haven't a clue as to what a

The easiest thing to do is put the lines

```
#ifndef Setpalette
#define Setpalette Setpallete
#endif Sepalette
```

right after

```
#include <osbind.h>
```

and your code will work with all ST compilers. The #ifndef ensures that
"if ain't broke you won't fix it."

|>

I have no answers to your questions but
you can probably avoid the problem in the following way:

Fopen - Fread x bytes - Fclose!!!
prompt
Fopen - Fwrite x bytes - Fclose
prompt
Fopen - Fseek to position x - Fread - Fclose
prompt
Fopen - Fseek to the end - Fwrite - Fclose
.
.
.

hope this helps,

>both time and memory efficient.

Oops, looks like someone broke into my account and posted something stupid!
I'll make sure I use better passwords in the future. :-)

Actually what I usually do in practice is something like

```
calloc((unsigned) (bigsize / 32), 32);
```

which will work for sizes up to 32*65536 bytes. You can always increase
the "chunking factor" here at the expense of a few wasted bytes allocated.
This is basically what you describe but "by hand."

Another caveat re: Malloc is that it takes a _long_ parameter:

```
Malloc(32L);
```

instead of

```
Malloc(32); /* <- This will cause bad things to happen */
```

This type of bug is particularly difficult to track down. It would be
nice if the os-binding for Malloc had a (long) typecast in it to solve
problems like these -- oh well.

>
>Any help is greatly appreciated!!!!
>

There seems to be some disagreement about scaling of metafiles among programs. I remember when I was working on a program to create metafiles, I could create them so OUTPRINT.PRG like them, Pagestream would import them, but they would be upside down, and Easydraw would squash them down to about a height of zero. By trial and error I guessed the scale Easydraw was using and had them imported properly, but I preferred Pagestream (pseudo-) compatibility, and so used that. I think you will have to play with the numbers you pass to vm_coords().

Hope I was helpful, and good luck.

Abacus Internals spells it Setpalette. (btw, palette is the proper spelling of the word, Webster says) I don't have my Lattice C 5 manuals handy, but I remember reading that they deliberately mispelled theirs (they call it Setpallete if I recall correctly) because they want to remain compatible with the original Atari bindings. Much as I dislike the seemingly slipshod original bindings, I would leave them that way so that if you distribute your code, everyone else does not have to change your code or their libraries.

I wouldn't have believed it a year ago when I bought it, but I now have to expand the memory on my Mega ST2. Those MIDI programs and essential utilities really eat up the memory! I would appreciate advice or pointers to references on the following topics:

1. Impressions of the Z*RAM Mega 2-to-4 board. Specifically, how reliable is it, and will the board get in the way of the expansion slots or an internal hard drive? Also, how likely is a solderless board to shake loose?

2. Companies that will install a memory upgrade by mail: experiences, reliability, cost, turnaround time and so forth.

3. Articles or instructions for a DIY memory upgrade. Listings of chips (with part numbers) and good sources for parts would be great. I know how to use a soldering pen, but it's been a while, so advice on how tricky the job is would also be useful.

4. In the "as long as I've got the hood up" department, I'd like to know how people who've upgraded from TOS V1.2 to V1.4 have fared. Was it more trouble than it was worth? Did you lose any program compatibility? Should I just hang around until the fabled STE Mega upgrade board comes along?

5. Is there a list of boards that make use of the Mega expansion slot?

6. Has anyone had experiences installing an internal hard drive in a Mega?

Of course there is always the option of unloading my Mega 2 and upgrading to a Mega STE...

Thoughts, opinions, dirty limericks welcome.

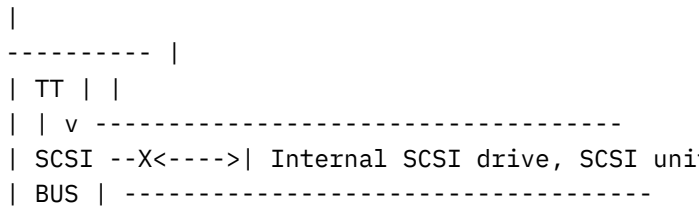
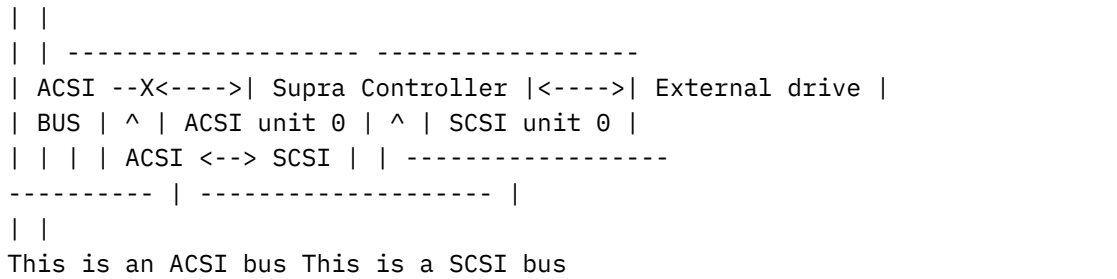
>backing storage :->

[I posted this earlier, but from the look of it the message didn't leave my
site.]

It's not the least bit wierd if you work through the logic of the busses.
The fatal flaw in your reasoning is that you think since both drives are
SCSI drives, they should have different SCSI unit numbers. What's actually
happening as far as the TT is concerned is that you have one SCSI drive and
one ACSI drive. The Supra drive is connected through a controller which
lets you plug the SCSI drive into the ACSI bus. The controller, in
essence, creates a tiny SCSI bus between it and the drive you connect to
it. This controller will only control one unit, and it has to be SCSI unit
0. The controller probably has a switch of its own, to tell it which ACSI
drive it should respond as.





If you add another Supra controller (or ICD controller or any SCSI-to-ACSI converter) to the ACSI bus, you would have to make it ACSI unit 1, but the drive it controls would still be SCSI unit 0, and there's no conflict because it's the only SCSI drive on the SCSI bus that the controller creates between itself and that drive.

Get the picture?

More minutae: HDX asks "SCSI or ACSI" when you select a drive; it's talking about SCSI or ACSI as the TT sees things, not necessarily which kind of mechanism it is. Almost all Atari drives are now SCSI drives with an ACSI-to-SCSI converter inside the case, where you don't see it. The Megafile 44 is a good example. Some used to be (and may still be) ST-506 drives with an ST506-to-ACSI converter inside the case, so don't count on one or the other without checking.

The chief difference between SCSI and ACSI in the TT is that the SCSI bus supports the full SCSI command set, and ACSI doesn't. One important command which ACSI does not support is "inquire capacity." When you can do "inquire capacity" you don't need to know anything else about the drive to format or partition it, ergo no wincap and no "click on the drive type" box. Wincap is still required for HDX to be able to format and partition some (all?) ACSI drives.

A final note: Mega STe's have an internal SCSI drive like TT's, but again, there is a SCSI-to-ACSI converter inside the box, so as far as TOS and HDX are concerned, it's an ACSI drive. Mega STe's don't really have SCSI, even though it kind of looks like they do.

2059. Cartridge port timing questions.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-24 00:32:05 UTC
From: swanee@megadata.mega.oz.au
Message-ID: <1991Apr24.003205.19880@megadata.mega.oz.au>
Source record: 48350

Does anyone know what the timing constraints of the cartridge port (ST, MEGA, STE and TT) are? Without a DTACK or DSACK signal being returned from the port, what are the data setup times required to meet the internal logic timing for data transfer.

Bearing this in mind, the TT runs at a much higher clock speed, so does the cartridge port now also have changed timing requirements over the ST's? If so, does this mean that most of the older devices using this port may no longer work?

Any information regarding this would be gratly appreciated.

Thanks in advance,
Geoff Swan.

From: rcb@netcom.COM
Message-ID: <1991Apr24.012040.22627@netcom.COM>
Source record: 48351

I am writing a GEM application based on a dialog box which occasionally has another dialog box written over it. When this 'pop-up' dialog box is done and I have called form_dial() the second time, instead of the original dialog box being restored, the desktop background is restored. Obviously, that doesn't 'cut it'. Is there a way for me to save the background and restore it when I'm done with the 'pop-up' dialog?

It looks like the problem is that GEM is not aware that my original dialog box is the background. How do I notify GEM that the background is not the original desktop? I've thought about doing a 'wind_set(0, WF_NEWDESK, ...)' but, if I do that, how would I get the original desktop back when my application is done?

Maybe insanity is the best answer. Any suggestions otherwise?

Date: 1991-04-24 03:36:43 UTC
From: heavy@zip.eecs.umich.edu
Message-ID: <1991Apr24.033643.12187@zip.eecs.umich.edu>
Source record: 48349

I seem to keep having problems with my C compilers. First I had Laser C, but I wanted ANSI so I bought Lattice 5, but it was quite buggy, so now I am using GNU C.

Anyway, I was using evnt_timer/evnt_multi to wait for a certain amount of time in Lattice C, then I would poll the serial port to see if anything had arrived...well, this worked fine for Lattice with a wait count of 10 (low-count). Well needless to say, this doesn't work fine for GNU C. Any amount of time over 0 is pathetically slow. I mean I set it to 100 for one particular instance and I would still be waiting for it to time-out if I hadn't rebooted. What's the deal? Does GNU use seconds instead of milli-seconds for its timer calls? I really need to have this work so I can look for bar-code reader input...it works in Lattice!!

Any help is greatly appreciated.

The desktop.inf is in ASCII, just use any old text editor, or even a
word processor with an "ASCII" mode, and change the text. You don't
have to stick to words of the same length either.

Just a hint, you must not debug the desktop.inf file with your
debugger, but its easier to edit the desktop.inf file with
a editor (for example wordplus or tempus).
There you can easily change the name of the thrash icon into
rubbish (don't bother about the size of the text).
The maximum size of an icon text is (so good as I remember it)
10. Thus you so long as your name does not exceed 10 characters
it will work. Try it!

Geert.

Just FYI, the ICD host adaptor is the only one for the ST that communicates the device sense codes to the user. This is quite nice. As for the error codes via LEDs, it would perhaps be simplest to call Seagate (you can call 1-800-555-1212 and get their 1-800 number). I have done this in the past, and they have responded with a Xerox of whatever info I needed. Just ask them for a manual for the device.

>0.

My reasoning is fine, thank you. Yes, what you describe above is intuitively obvious after knowing that both drives needed to be set to 0. What is less obvious is why the Supra HAD to be set to 0. My ICD host adaptor will allow me to set the SCSI device id to whatever I want, and will still find the drive at boot time. I can hook multiple drives up to it, etc. Thus, I make the following assertion: there are two logically seperate busses on the TT (which concern fixed disks): a pure SCSI and an ASCI. Each is independent in the sense of SCSI device id numbers, so each can have a device 0 without conflict. My question (based on this assertion) is this: Why did the Supra drive _require_ SCSI id 0? It was the only device on that "bus"? In other words, do the SCSI id numbers on a bus have to start with 0, then increment by one? Could I have a device 0, then a device 4? If not, why? This has been successfully done by both Supra and ICD (and Atari, I thought). If so, then is the restriction only on the first SCSI device (ie does a device 0 have to exist, but other devices need not be sequentially numbered)?

Another way to look at the question is this: What need be considered when hooking up multiple ASCI devices (consisting of host adaptor and SCSI device) to the TT? How must the SCSI id numbers be picked for all drives to work? It is inexcusable that this information was not included in the TT manual. For example, my hard disk was set to SCSI id 1 when I bought it. Thus, were I to get a TT (and without the benifit of helping my friend) I would not be able to get the damn thing to work without a phone call to Atari. Since this computer is a logical upgrade from the ST architecture, all information needed to "upgrade" should be included in the manual!!!!!!

If anybody in Europe has the KAOS TOS 1.4 fix files, it would be greatly appreciated if they could upload them to atari.archive.umich.edu. Talk has been buzzing across the pond here in North America about KAOS TOS (in the FoReM & ///Turbo x-nets), and many people would like to get these fix files for TOS 1.4.

BTW, what kind of bugs were fixed in KAOS TOS 1.4 that makes it so much better than the regular TOS 1.4?

>>than 0? I can see that if TT SCSI and ASCI are seperate buses then it is
>>ok to use the same id. Does this meen that the TT ASCI port only

On my Mega ST... I have no SCSI 0 drive. I use scsi 4 and 5 so I can
daisy chain a friends scsi 0 drive and still access my own disks.
But I can still boot... and use my hard disks w/o any SCSI 0 device
attached.

The fellow you've been chatting with says the TT won't recognize SCSI devices
1-7 on the ASCI bus, at least not without an SCSI 0 in place. Device 0 MUST
be used for the first device. Why????

You should write your application so that it uses AES - i.e. use evnt_mesag()
or envt_multi() calls. This way, when you free up a patch of screen where your
dialog used to be with the form_dial() call, the AES will send you a message to
tell you what area of the screen needs redrawing. (It's up to you to do the
redrawing - if your dialog is an object tree, this is no problem.)

If all this is news to you, then I would suggest Tim Oren's ProGEM series of
articles as a damn decent way to teach you about these things. Certainly an
improvement on my ramblings...

There are a couple of other ways to handle this. One that I use is to save the screen area under the dialog box when you put it up and restore it when you put it back, using the blit routines. Specifically, you can use the vro_copyfm() routines. Or you can save each dialog box using the same technique and restore all of it when you get a redraw message. Or you can save the whole screen, although this uses 32K of memory.

As far is insanity, I came pretty close when I was first trying to implement this stuff! :^)

No, the problem is that the 'evnt_timer()' and 'evnt_multi() with
timer' calls in GNU C's gemlib are buggy. The fix is very simple if
you have source code for gemlib - just swap the word order of the
int_in[] parameters. I have sent this fix to bammi as well, so you
should see it in a future release of gemlib.

2074. Can't get Setpallete() to work.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-24 20:22:44 UTC
From: marco@sys6626.bison.mb.ca
Message-ID: <LoiX11w164w@sys6626.bison.mb.ca>
Source record: 48372

Here's the code I've been trying to use to blank (black) my screen:

```
------------------------------------------------------------------------
#include <stdio.h>
#include <osbind.h>

main()
{
int i, pal;
for (i=0;i<16;i++)
pal = i;
Setpallete(pal);
}
------------------------------------------------------------------------
```

I have tried everything, the spelling, everything. Am I totally on the wrong track with this (the purpose, by the way, is to blank the screen to prevent burn in). The above program just inverts the screen, when I click on the Control panel ACC it is re-inverted back to black on white and the first color in the pallete is set all 3 bars at the top. When I pull them down the screen goes white on black and running the program does nothing. Any suggestions?

From: miskinis@aisg.enet.dec.com
Message-ID: <4525@ryn.mro4.dec.com>
Source record: 48365

Hi,

Things have got quite busy at work, and I haven't been spending
as much time on as the ST that I'd really like to...

I *HAVE NOT* been successful at writing an interrupt handler
that allows "normal" operation of mouse and/or keyboard.

It seems that only a few people have done this, and as soon
as they do, they market something using it. This is what it seems
like anyway, since there's not too much discussion of it anywhere.

There are several great sequencers out there, so I know it's
possible...

If finances allow, I'm going to try to become a registered
Atari developer. I tried getting some technical support from Atari
in the past, but as soon as I say I'm not a registered developer,
they really don't want to talk to me...

PLEASE! If there's anyone out there with code that does
this, PLEASE PLEASE post it!

Thanks,

John

2078. DBMan Programming question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-25 02:34:51 UTC
From: swood@vela.acs.oakland.edu
Message-ID: <6118@vela.acs.oakland.edu>
Source record: 48364

I am about to delve into the world of DBman and DataBase III+ style programming

I am hoping to be able to do a search of a couple of various feilds in my database. I have set up a couple text feilds that are made up of letters and/or ?'s. I have a list of questions that I ask of the people that I am adding to the database, and if they apply I put a letter, if they do not, I put a question mark (I did this, as that is one of the wildcards they mentioned)

a finished string might look like : 'AB?D?F?H??KLM?O???ST??WX?Z'
for what of course would be complete as : 'ABCDEFGHIJKLMNOPQRSTUVWXYZ'

I am going to be writing a program then to find the closest match(es) sort of like a dating service, but not quite. Anyone have any suggestions on how to go about this?

2080. Re: Problem with my C program to copy files between floppies

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-25 05:44:17 UTC
From: umochock@ccu.umanitoba.ca
Message-ID: <1991Apr25.054417.21973@ccu.umanitoba.ca>
Source record: 48366

To those of you that answered my plea: thanks! A summary of your ideas follows.

Several people mentioned using drives a: and b: so the GEM box to switch disks would appear. From the beginning, I was using a: for the source and b: for the destination file but that box never appeared.

Thinking it maybe was something gulam was doing, I tried running it from the desktop -- still no boxes.

On a hunch, I renamed the executable from .ttp to .prg and well-what-da-ya-know it worked! ---- but only from the desktop, not inside gulam. Try ls a:; ls b: in gulam -- I don't get the box. I tried b: in mupfel though and I did get the box to switch disks.

Gulam must be suppressing this box. How can I re-activate the box?

Others mentioned flushing the I/O buffers with Mediach() and making sure the ST got the media change with Getbpb(). This didn't make a difference -- still no alert box.

The adventure continues....

[re multiple dialog boxes]

>There are a couple of other ways to handle this. One that I use is to save the
>screen area under the dialog box when you put it up and restore it when you
>put it back, using the blit routines. Specifically, you can use the
>vro_copyfm() routines. Or you can save each dialog box using the same technique
>and restore all of it when you get a redraw message. Or you can save the whole
>screen, although this uses 32K of memory.

The trouble with this is, you only get 1 level of nesting (or another 32K
every time you open another dialog on top of an old one!).

A far better, and easier method is to just redraw the form AFTER the nested
form is complete. Just use objc_draw for this purpose.

I do recommend you read Tim Oren's ProGEM series - they are at atari.archive.

You asked about setting your own desktop object, here's how:

First, to set an object as the new desktop:
(note, this is hacked from Modula-2, so beware)

```
NewDesk=14
rsrc_gaddr(tree,FormNumber,&Form);
wind_set(0,NewDesk,Form,0);
```

To go back to the original desktop:

```
wind_set(0,NewDesk,0,0);
```

2083. *** HELP! Annoying Verticle line screen garbage! ***

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-25 09:10:33 UTC
From: sean@ccwf.cc.utexas.edu
Message-ID: <47867@ut-emx.uucp>
Source record: 48376

OK, here's the story so far:

Occasionally my ST Color Monitor SC1224 fills up with vericle lines along the left side of every other character column. In lo rez that means 20 verticle lines, in med rez it's 40.

But this only occurs in text areas. If I boot from my hard drive using ICD's host adapter, the screen's starts out ok but once the GEM desktop appears so do the annoying lines. Then my desktop picture arrives covering up the lines. The picture looks fine except for some traces of the lines on the picture's extream borders. Then when the drive windows open up, the verticle lines are back, but now only on the inside of the drive boxes.

At first I thought it might be anything from loose connections, to my monitor master (although I am currently sans Monochrome - got one to sell?), to a hard drive virus (yeeeks!). So I turned everything off for 5+ minutes, disconnected my hard drive, connected the Color monitor directly into my Mega4, and booted with a virus free disk. Sure enough, the same problem.

Essentially, where ever text is or can be displayed (including editable text fields) are verticle lines on every other character's left side. This includes the space character. Some times these lines preclude the character entirely and I end up with lines like:

```
| | | | | | | | | | | | | | | | | | | | | | | | | |
| | | | | |l|c| |e|e|t| |o|t|n|e|)| | | | | | | | |
| | | | | | | | | | | | | | | | | | | | | | | | | |
```

(Click here to continue)

It's happened three times in as many days for seemingly random reasons and lasts anywhere from a few minutes to an hour or more. The first time I recall this happening was during a large hard disk to hard disk copy. The size was about 4 megs of information, with <300 files and folders. (Yes I have plenty of extra folders allocated (2500) thru ICD's software.) During the middle of copying and updating, the copy window (`currently copying filename to filename') gets the lines. Another time was on returning to the desktop from an application (application name forgotten).

No amout of re-booting, jostling of cables, or praying to local deities helps what so-ever.

Any clues?

Thanks in advance.

>better than the regular TOS 1.4?

Grow and Shrink boxes have been removed, and the code that forces a redraw
of the window when it have been sized, also have been removed...
(therefor it isn't compatible with programs that uses fixed sized windows,
eg a window that is limited in the lower right-hand corner).

The program is NOT PD or SHAREWARE, you buy it as a upgrade to TOS1.04 on
disc. On the disc is a program that modifyes the TOS in rom and saves the
patched code on disc, ready for the Eprom-programmer...
Price is around 89 DM.

I tried this and it worked fine. I will do this, but as an
alternative, I could go back to what I was doing before (redrawing my
original object when the dialog is finished). It's just a lot nicer
to have system support, instead of having to program everything
yourself.

In general, this is not a fix. I have seen allocators which call malloc
from calloc after multiplying the two args together AS INTS, not longs. So
this does you no good at all. Some compilers work and some don't in this
respect. You pays your money and you takes your chances.

>You also can use lalloc, which works like the library malloc()
>function except that it requires a long argument. (Be sure to include

Much better solution, if your library has lalloc. Some have lmalloc, so try
both. (I forget if the original poster said what compiler/library he was
using.)

>> In general it is VERY WISE to avoid using the bios Malloc and Free and
>> use the malloc, calloc, and free provided with your compiler of

Humph. TOS 1.4 and upwards have NO PROBLEMS with Malloc that have been
reported to me.

>separate means.

Sigh. I guess there's nothing much to say about this... Are you SURE you can't use Pexec to execute the program, too? Try mode 4, then Mfree the environment and basepage (in that order) that were created when you used Pexec mode 3 or 5 (whichever you used). Starting with TOS 1.4, you can use Pexec mode 6: mode 3 plus mode 6 equals mode zero. The return code from mode 6 will be the return code from the process.

>Q: What I want to know is the return code passed back in D0, on the

> available at the time of the call to the Terminate Handler?
> I'm trying to make mods to the Sozobon Debugger to handle printing
> the return values before it exits.

The return code is not available at the terminate handler. The return code is the argument to Pterm() or Ptermres(), or zero for Pterm0(). If you want, I guess you could catch those calls and squirrel away the return code before passing the call on to GEMDOS.

>Q: If I've used Pexec() to load a program and I'm handling the
> execution of parts of that program. How can I tell the system
> to terminate that child process. Basically I want a kill() or
> a ptrace(PT_KILL_PID, child, 0, 0) so that I can add a restart
> command.

You have to execute a Pterm() call while the process is the "current process" as far as GEMDOS is concerned.

Hi me again...

After reading my statement that there are many adjustments inside the SC1224, some of you can't believe that I ACTUALLY made the adjustments when the monitor was ON, and my ST had an image on it.

Method: Turn one adjustment a little one way, and watched the screen, if it did something good, I turned it some more, if it did something bad, I turned it back.

Since I had already been stupid enough to make some adjustments, I fiddled with the rest of them and enlarged the screen, and played with the color.

AAron@sun.soe.clarkson.edu
I might be considered careless, but I felt daring and confident.
If you try this, you can be considered careless too!

In refrence to my suggestion to avoid Bios Malloc, Allan Pratt writes:
>
>Humph. TOS 1.4 and upwards have NO PROBLEMS with Malloc that have been
>reported to me.

This has little bearing on the fact that TOS 1.2 and downwards DO have problems. I want my software to run on all ST's. Please understand that I wasn't trying to criticize you; in fact I realize that the whole situation has been made worse for you because lots of programmmers have _relied_ on the earlier bugs.

Using Unix-compatible malloc routines provided in a compiler's libc.a is better than using Atari's Malloc binding because:

1) It works on all ST's (assuming said malloc is properly written)
2) It's more portable (does not assume longs are bigger than ints)
3) It's not prone to Malloc(1) versus Malloc(1L) bugs

On the other hand, the drawbacks are:

1) It's slower
2) It adds code size to your executable

It would be great if I could assume all ST's out there were running TOS 1.4, but I can't. I should think you'd want us to be writing stuff that is maximally machine-indpendent. I'm not being snide here; this is a thorny issue that ST programmers have to deal with. I've written lots of code using Malloc and lots of code using malloc -- I've never had problems with the Dlibs malloc routine, while the Bios Malloc (under TOS 1.2, I admit) caused me tremendous grief.

If you thought I was just making some off the cuff slanderous remark, you were mistaken. I posted the advice I gave based on 4 years of heavy-duty ST programming, simply hoping to prevent others from wasting their time dealing with bugs and ideosyncracies I learned about the hard way several years ago.

If Atari wants my opinion (which they probably don't), I think they should release "official" source code for malloc, calloc, and lalloc that works on all ST's and coalesces memory correctly. (Perhaps this would check the TOS version and just call the Bios for 1.4 and up.) Then we'd have a common denominator. This would also solve the problem of how to allocate more than 64K at a time.

If you're drawing `custom' objects in your dialog box that can't be managed with the given set of boxes, buttons, etc, you should consider using a G_PROGDEF object: the ob_spec should then point at a data structure (can't remember the name) which contains the address of a routine to do the custom drawing, and a longword parameter. This way you can still use objc_draw(), which will automatically use your code to draw your custom object. Again, I would recommend Tim Oren's ProGEM for a better explanation of this.

From: arditi@taloa.unice.fr
Message-ID: <89@taloa.unice.fr>
Source record: 48389

I have e strange problem that I will try to explain...

I did a program wich starting address is $8 so it overlays all interrupt
vectors. Of course I set SR to $2700 (No interrupts should happen).
On Atari STE and all STF except the serie which was sold just before STF
had a double sided drive, my code works well. But with this serie it bugs.
I discovered that on that serie, a parasite interrupt (I don't remember
its number) happens.

So I would know if someone knows what starts this interrupt on ST and why
it does not work same on all different mother cards.
I think a good technician, a member of Atari Corp. could answer me.

Thank you.

PS.: Excuse me, I'm French so my English is...you know !

I believe I *did* see this when I was running Tos 1.0, but things are
rather fuzzy now - it's been a while since I got 1.4. It would bomb
if I got really fast with the backspace key.

>them static (non-stack) strings. Does anybody remember what to do so
>this doesn't happen?

The suspected problem was in fact the true problem: The strings were on
the stack, so when AES re-drew the windows the address pointed at crud.
The problem was that TDI Modula makes a local copy of arguments that are
ARRAY OF CHAR if they're not VAR.

>If I create a window with WindowCreate(...Closer+InfoLine+Name...), then
>do WindowSet(...Closer+Name...) and then WindowGet(...WorkXYWH,x,y,w,h),

My custom objects were on the background window, not the dialog box. I haven't used the PROGDEF pointer before, however. Does it point to executable code or just some sort of bitmap? (It would be kind of nifty if it pointed to an executable routine).

I'll also check out ProGEM. I know you posted a pointer to it, and I lost it, where can I find it?

Thanks

From: healy@cod.NOSC.MIL
Message-ID: <3016@cod.NOSC.MIL>
Source record: 48447

Regarding Claus Brod's suggestion for getting one or the other mouse button with event_mbutton or event_multi, thanks, it helped me out.

I am having a problem that hopefully someone else has already encountered and solved. I am running TOS1.4 on a 1040STF with 4 megs, using LASER C 1.0.

When I execute my program from within the Laser shell, the event_multi call works fine. When I execute my program from the desktop, the event_multi call will not receive mouse button events. It's as if something is intercepting them. My event_multi call is checking for keyboard and mouse button input and the keyboard input works. Using event_mbutton instead of event_multi has no effect.

I have tried disabling all the junk in my auto folder, to no effect. It seems weird that something that runs ok out of a shell wouldn't run off the desktop.

If the solution is to upgrade Laser C, I would like to. Does anyone know Megamax's phone # & address. I have written to the address in my manual requesting an upgrade but have received no reply.

Thanks

Mike Healy

2111. Getting ASCII value from scancode

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-26 23:25:19 UTC
From: heavy@zip.eecs.umich.edu
Message-ID: <1991Apr26.232519.12216@zip.eecs.umich.edu>
Source record: 48444

I am having a problem. It is quite easy to get the scancode
for a key being pressed (by using evnt_keybd/envt_multi), but
it is a little harder if you just want the ASCII value. For
instance:

it is possible to press any ALT+<key> sequence in my program.
When I get a keyboard event, I get the keyboard state from
vq_key_s() (i.e. shift/control/alt), but I get the scancode
from evnt_keybd/multi. So i guess what I am asking, is there
anyway to go from scancode to ASCII without having to define
all the values in my program?

Well, I have TOS 1.4 and made a text editor program called SEDT crash.
When I reported the problem to the author of SEDT he traced it back to
the fact that his library was using Malloc directly for all allocations.
When he changed to a different memory allocation algorithm the problem
went away.

Also I just rewrote the memory allocation algorithm for a Modula-2 I have that
appeared to be using Malloc directly... a short test program using their
library crashed the computer (2 bombs) after a bit over 800 small allocations.
My rewrite made it to 10000 small allocations (from a single large Malloced
block) with no problems.

When you press 'normal' keys (without ALT), the ASCII code is in the least significant byte of the scan-code. With ALT, the least significant byte is 0. So, it looks like getting the ASCII would involve a table which maps the most significant byte of the scan-code to ASCII. Unfortunately, this scan-code byte is based on the QWERTY positioning of the keys.

It's true that it would be nice if the non-ASCII code for ALT keys were, say, the same least significant 7 bits (as the corresponding ASCII character) with the 8'th bit set, but ... After all, why make it hard on the people who write typing tutors?

You should use evnt_keybd() which returns an integer.

Now, the high-order byte contains the scan code of the key pressed,
and the low-order byte contains the ASCII code.

In article <91115.122751ONM07@DMSWWU1A.BITNET> ONM07@DMSWWU1A.BITNET (Julian F. Reschke) writes:

>First of all: who said that KAOS 1.4.2 is so much better than TOS 1.04?

I guess, at least two, namely the developers :-)
But seriously, aren't there still some deficiencies which could be cured in TOS 1.4 (B.t.w. why 1.04?)? And why is KAOS praised to be the ultimate TOS 1.4 patch, which is my impression while looking at some reviews in german magazines? Two arguments I would accept are:
- improvements are mainly marginal
- degree of incompatibility is to high.
Any advice is appreciated.
Latest news (I know of): there's no EPROM service at the time, due to licence problems.

>>keeps spinning.

According to the ST{251,277,296}N Product Manual (which *might* be similar to
the ST157N as far as blink codes):

One blink: Microprocessor/Internal Memory Test failure
Two blinks: Microprocessor ROM checksum
Three blinks: Controller chip failed to initialize
Four blinks: Controller program RAM test
Five blinks: Data buffer RAM test
Six blinks: Drive is unable to reach and maintain proper spindle speed
Eight blinks: The controller is unable to read its own control microcode
from the drive.
Nine blinks: The control microcode can be read but is corrupted.

These conditions all have corresponding sense codes.

Yes, it does, but not if someone presses 'ATL+A'. The low order bits in this case are zero. I want to be able to see that they pressed 'A' while holding down 'ATL'. I can get the keyboard state with vq_key_s() (this tells me if they are holding down shift/control/alt), but what I need to know now is what ASCII key they pressed with it. So if I can get some method to find this out, I won'd need some big if-then-else-if structure to key for a specific value...for instance, 'ATL+A' = 0x1e00, 'ATL+B' = 0x3000. Now the only what I know which ASCII key they pressed is by having some code like:

```
if (key == 0x1e00)
c = 'A';
else if (key == 0x3000)
c = 'B';
.
.
.
```

ad infinitum

I don't really want to do this, but it might be necessary.

Message-ID: <1991Apr28.014020.3838@lonex.radc.af.mil>
Source record: 48324

A friend and I were considering undertaking our first joint programming effort, and though that as a shake-down project, we would try and build a simple "hot-key" program that would allow one to swap between low-med resolution with the stroke of a key.

I seem to remember reading something here in months past about the subject of changing resolutions within programs, and was wondering if someone who remebers the gist of the conversations would be willing to give me a brief summary of what was said then.

Also, is there any way to force a resolution change WITHOUT a resulting reboot of the system. I mean, from desktop (med) to desktop (low) and vice-versa?

Any help would be appreciated.

Right. Unfortunately, the low-order bytes are zero in lots of other cases:
function keys and cursor keys, to name two.

Here's what I do when I see a null byte. First, kbshift(-1) & 8 tells me
if ALT is depressed. Now you take the scancode and look it up again in the
key mapping table. The address of this table is handed to you as the
return value of keytbl(-1L, -1L, -1L), which you need call only once; this
points to a vector of pointers to the unshift, shift and capslock tables
(each 128 bytes indexed by scancode).

Now all you have to do is undo the GSX nonsense -- hello? Are you still
there? -- best to experiment with values between '1' and '='; I get
terribly confused at this point.

Pleasure. In startup:

```
char **keytb;
char *ktunshift, *ktshift;

keytp = (char **)Keytbl(-1L, -1L, -1L);
/* Setting [2] to same as [0] forces capslock to be ignored... */
ktunshift = keytp[2] = keytp[0];
ktshift = keytp[1];

...

/* Now, if you have the scancode right justified in int scode... */

shifts = Getshift(); /* i.e. kbshift(-1);

if (shifts & 8) { /* ALT */

if (scode >= 0x78) /* Allan Pratt explained this once, but... */
/* GSX correction: */
scode -= 0x76;

/* This code ignores the capslock key. Use shifts & 0x10 to look at it. */
ch = ((shifts & 3)?ktshift:ktunshift)[scode];

if (shifts & 4) /* CTRL */
ch &= 0x1f;

if (using_full_8_bits)
ch |= 0x80;
else
emit('\033'); /* Use esc-char as alias for 8th bit */
}

emit(ch);
```

Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

(for those who care --> follow-ups directed towards
comp.sys.atari.st.tech where they belong)

This is really a hypothetical question......
There is a program called "viola" that is sort of an X11 (x
windows) version of hypercard.

Does anybody have any experience porting programs built on the X11
model of client-server programs to GEM (or anything else) on the ST ?
(I know..... I COULD wait until I could afford a TT and *nix..)

I'm pretty sure it's been done already --> for example... the program
contained in texdraw.lzh in /atari/tex on atari.archive.umich.edu ...

Anyone got any ideas ??? Comments ???

2123. Help!! Monitor screen "shakes"

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-28 21:59:31 UTC
From: vovut@prism.cs.orst.edu
Message-ID: <1991Apr28.215931.8719@lynx.CS.ORST.EDU>
Source record: 48459

I'm having more problems with my monochrome monitor again. A few weeks ago my monitor "died". Luckily a few people on the network informed me that all I had to do was to replace several diodes. I did that and it has worked fine.

A few days ago the picture started to "shake". The entire screen vibrates, with the left side being more noticeable.

I didn't replace the diodes in the monitor with the *exact* diodes, but the salesperson at the electronics shop said the ones I have will work. I think the differene is that the ones I'm using now have a higher voltage rating (??).

Has anybody seen this problem? Is there a fix, or do I need to buy another monitor?

Thanks in advance.

do you have an external power supply, and where do you put it? a few
weeks ago i set my system up after unpacking, and set the "big black
brick" next to the monitor. the display quivvered, just enough to
be annoying and worrying,until i thought to move the PS. fine now.

This is normal SCREENMGR behavior. In fact, the KAOS programmers tried
to add a 'smart redraw' option to their TOS version. It turned out that
quite a few programs didn't like this and messes up their redraw.

I don't understand though why one would like to redraw other program's
windows, like those of a DA. Can you be more explicit?

You don't have to call kbshift; the keyboard status is returned in one of
the evnt_multi return parameters. Use this value instead of the kbshift
value to be sure to get a consistent view of the things going on at the
keyboard and in the AES keyboard buffer.

2129. ROM sockets in a Mega ST 2

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-29 08:34:47 UTC
From: felner@nessie.cs.id.ethz.ch
Message-ID: <1991Apr29.083447.27132@bernina.ethz.ch>
Source record: 48475

I want to upgrade a friend's Mega ST 2 from Blitter TOS to TOS 1.4. I have never opened a Mega ST myself before, but I know that there are motherboards for 2 ROM chips and others for 6 ROM chips (as in the old 520s). Last night I opened his machine and I found 6 28-pin ROM sockets, labelled LO-0 to LO-2 and HI-0 to HI-2. But there are only two ROMs in the sockets labelled LO-0 and HI-0 !?!? I am confused, but I proceed and put 6 27256 EPROMS with TOS 1.4 in those 6 sockets. I boot, the screen turns white, the floppy light flashes and the machine reboots and reboots and reboots ...

Questions:

Why are there 6 sockets if the ROMs only need 2? Or do I have both options, 2 and 6 ROM chips? If so, how do I change from one to the other? Is there a jumper somewhere? I would prefer the 6 chips solution. If I have to stick with 2 chips, which EPROM type do I need?

The revision number of the motherboard is 5.0. The machine is about 2-3 years old.

> c = 'B';
> .
> .
> .
```

```
> ad infinitum
```

>I don't really want to do this, but it might be necessary.

How about this code:

```
/* correct this table to the correct values. *
* From your example it seems that position 0x1e should have 'A' */
char alt_to_ascii[256] = { 'a', 'b', 'c', ... };
```

```
if ((key & 0xff) == 0) /* is the low byte 0? */
c = alt_to_ascii[key >> 8];
else
c = key && 0xff;
```

```
Or otherwise:
switch (key)
{case 0x1e00:
c = 'A';
break;
case 0x3000:
c = 'B';
break;
.
.
```

.

ad infinitum

Just some thoughts

> |> background is restored. Obviously, that doesn't 'cut it'. Is there a
> |> way for me to save the background and restore it when I'm done with
> |> the 'pop-up' dialog?

GEM's form_dial is just a way to tell the screen manager that it has
to force the application to redraw it's screen.

Since dialogs are not windows, you have to use code like this:

form_center(dial1,...);
form_center(popup,...);

redraw=TRUE;
form_dial(FMD_START,dial1....);

do{
if(redraw)
{
objc_draw(dial1,....);
redraw=FALSE;
}

ex=form_do(dial1...) & 0x7fff;

switch(ex)
{
case CALLPOP:
form_dial(FMD_START,popup...); /* not needed if popup is < dial */
objc_draw(popup,....);
form_do(popup,....);
form_dial(FMD_FINISH,popup....); /* "" */
redraw=TRUE;
break;

case ANYTHING:
form_alert(1,"[0][What you want][XXX]");
break;
}

} while(ex != EXDIAL1);

form_dial(FMD_FINISH,dial1....);
```

I hacked this from memory because my sources are on backup for the moment,
but that's the way my applications handle it.

Notes:
Alerts restore there bg automatically.
I discovered that form_dial(START/FINISH) may be used out of specific order
but I never found this being official, be aware.

Hope that helps,
Bjoern

True; my code assumes Bconin(), and I had missed the fact that the original
question had referenced evnt_multi().

> Use this value instead of the kbshift
>value to be sure to get a consistent view of the things going on at the
>keyboard and in the AES keyboard buffer.

Yes, there is a window between Bconin() and Kbshift(), but it's an utterly
unimportant one. There's also a little overhead in the extra BIOS call.
Incidentally, what does evnt_multi() do; does it call Kbshift(), or does it
know where the BIOS stores the current shift bits? Just wondering.

2134. Need help with clock!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-29 13:20:04 UTC
From: mpnolan@vax1.tcd.ie
Message-ID: <1991Apr29.132004.1@vax1.tcd.ie>
Source record: 48318

I need help/advice on a problem....

-I want to set up a clock. A simple interrupt driven clock.
The problem is, I don't know what time registers to use.
There are numerous hardware time registers in the ST, but I'm
having difficulty enabling them.

-I have 'ST INTERNALS', which has information on most of the chips,
and I am using it as reference.

Thanks in advance,
Mark Nolan.

Has anybody seen the new mag, 'The ONE for the ST'?It seems to be quite good..

So that 6 new ROMs can be placed.
> Or do I have both options,
Yes, you do.
> 2 and 6 ROM chips? If so, how do I change from one to the other? Is there a
> jumper somewhere?
6 ROMs are 256 stuff while 2 ROMs are 1 megabit stuff. You must 'short'
pin 2 and 12 of U12 (pluck off the IC first and replace a socket so that
future TOS can be fitted in 2 chips.) As for jumpers w2 and w3, replace
the caps the other way.
> I would prefer the 6 chips solution. If I have to stick with
> 2 chips, which EPROM type do I need?
The same type you have had of course.
The Best Electronics of San Jose sell a plug-in board by Wizztronics
that looks after two different sets of ROMs(2 and 2, 2 and 6, or 6 and 6
chips) for $69.95. It will allow you to switch between to different OSes.
I haven't tried it but I can well imagine it.

>...

I have similiar problems with my ST 520+ (TOS 1.4, but also with 1.0)
and mono monitor SM124 with any configuration of auto-prgs or accs.

From time to time 8 black vertical black stripes appear on the screen
hiding parts of the display. The stripes go from top to bottom. Each
stripe has a width of 2 characters (16 pixels), the space between is 8
chars, the first stripe is after 6 (sometimes after 2 chars) and the
last one is at the right border of the screen. The missing chars of the
right border appear at the left border of the screen with one pixel
shifted vertically down. Quite strange, isn't it?

For example

This is at the left border .... This is at the right border

displays like:

```
|| || || || || ||
erThis i||at the l||t border||... Thi||is at th||right bo||
|| || || || || ||
```

This effect occasionally comes out when:
- starting or finishing TEMPUS,
- ViewGIF displays a picture,
- SysMon is invoked,
- tracing over certain TRAPs with MonST debugger (couldn't find out
which in special).

I have never seen these stripes when connecting my TV as color monitor
to my ST, but I
don't use color mode often.
Normally only rebooting helps to get rid of the stripes. Sometimes the
responsible programs restore a stripped screen again, but in this case,
sometimes the chars from right remain at the left side.

Any suggestions?
Thanks in advance.

2140. TOS ROM switch

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-29 16:39:26 UTC
From: sslee@polyslo.CalPoly.EDU
Message-ID: <281c4c3e.26ba@petunia.CalPoly.EDU>
Source record: 48468

I'm finally thinking about getting the TOS 1.4 ROMS, however I would still like to get access to the old TOS 1.0 ROMS I have now. (Yes, there are some programs I have that insist on TOS 1.0.)

Anyway, what I would like to do is add a simple switch to flip between the ROMS. Sounds easy, right? I'm sure others have done something like this and could fill me in on the details of what problems I may encounter.

Thanks,
Steven

>The fellow you've been chatting with says the TT won't recognize SCSI devices
>1-7 on the ASCI bus, at least not without an SCSI 0 in place. Device 0 MUST
>be used for the first device. Why????

[Am I "the fellow [he's] been chatting with"?]

I can't speak for what SCSI unit numbers ICD or Supra adaptors will or
won't recognize. From the data presented here, it sounds like ICD will
handle any SCSI unit number on the drive, and Supra will only talk to SCSI
unit zero. The latter is not unreasonable -- if you've got only one drive
on a SCSI-to-ACSI converter, why include the logic to talk to an arbitrary
SCSI device number? It would mean logic in the adaptor to see what SCSI
drives are out there.

I have even heard of some adaptors which look at the SCSI unit number of
the drive that's connected, and configure themselves as that ACSI unit
number, further confusing the issue.

As for the ST/TT side of the bus, you have to start with zero on each bus
and increment by one for each drive you connect to that bus. (Remember,
that's unit numbers as the computer sees them, not as the adaptor sees the
disk it's actually talking to.) The reasons for this are kind of involved,
and I don't want to go into them; just take my word for it and carry on.

I hope this clears up the questions about busses and unit numbers, and we
can get on with our lives.

That's "vertical," not "verticle."

Take your machine to a dealer. There's something wrong inside. A dealer
should be able to diagnose, attempt a fix, and ultimately repair or replace
the motherboard. If the machine is out of warranty he will probably want
to charge you something. Let him.

marco@sys6626.bison.mb.ca (Marco) writes:

>Here's the code I've been trying to use to blank (black) my screen:
>--
>#include <stdio.h>
>#include <osbind.h>

>main()
>{
>int i, pal;
>for (i=0;i<16;i++)
> pal = i;
>Setpallete(pal);
>}

This won't work because Setpallete (sic) takes a LONG argument which is a
POINTER to an ARRAY of 16 INT's. Check those types in the documentation!
If you look at your code again I think you'll realize that it doesn't make
any sense at all.

```
main()
{
int i, pal[16];
for (i=0; i<16; i++)
pal[i] = 0;
Setpallete(pal);
}
```

Setpallete is a misspelling of Setpallete, and is that way because Atari's
original docs and include files spelled it wrong in the first place.
As has been pointed out, this is now retained by most compilers.

A caveat for Setpallete users: the above program is unreliable because
Setpallete copies its argument to a variable, and the palette registers are
loaded from the 16 int's found there AT THE NEXT VBLANK. Since the above
program has terminated by the time the next VBLANK rolls around, that means
this memory is not owned by anybody, violating the commandment "Thou shalt
not mess with memory thou ownest not." I know the "program" is just an
example of this poor slob's problem, but it bears repeating that Setpallete
is a delayed-action call.

Have you relocated your system/monitor, or placed any new equipment in the vicinity? The SM124 is _extremely_ sensitive to magnetic fields. Even a small magnet placed next to the monitor will sometimes cause an annoying jitter in the display; a small flourescent lamp next to the monitor will cause it to go crazy. When I first got my ST the display sometimes jittered and it took me two months to track down the source of the problem. There was nothing in my office that made any difference, and no wiring buried in the wall, etc.; but the jitters got really bad whenever a guy on the other side of the building turned on his electric heater. It turned out that the electrical service for the building was on the wall _outside_ my office, about 1-1/2 feet from my monitor, and the heater was drawing enough extra current through the service to cause the problem.

Anyway, try moving your monitor to the center of the room or something like that to rule out magnetic interference.

Andreas Schuch says his screen goes funny when
> - starting or finishing TEMPUS,
> - ViewGIF displays a picture,
> - SysMon is invoked,
> - tracing over certain TRAPs with MonST debugger (couldn't find out
> which in special).
(deleted)
Aha! The monitor seems OK. It looks like a problem of poorly written
software that don't look after other interrupt handlers well. To test
whether the problem comes from the screen memory or the monitor, read
the address of the funny picture while it is shown on the screen.
You may need a pocket calculator to work out where because TOS tells us
only of the base of the screen memory. One thing I do often is to use
the 'pokew' command of GULAAM. Your debugger should be more versatile.
If the source of the trouble is suspected to bugs of the software,
you can ask the bug fix from the vendor.
Hope this might fix the problem.

P.S. The easiest way to detect the problem is to do the same thing on
someone else's monitor or machine.

I propose a solution:

Program both TOS ROM sets into 27512 ROMs and use the MSB of the address
to select between TOS versions. This would involve programming TOS 1.0
into the bottom (or top) half of the '512 ROMs and TOS 1.4 into the other
half. Pin 1 of each 27512 can be used to select the TOS version.
The 27512 has the same pinout as the 27256 except for pin 1, so the existing
ROM sockets can be used, except that pin 1 of each '512 needs to be bent
90 degrees and soldered together and connected to a switch from either
+5V or GND.

2147. programming and MIDI

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-30 00:16:02 UTC
From: driesse@qucis.queensu.CA
Message-ID: <1885@qusunb.queensu.CA>
Source record: 48292

Since there are GEMDOS functions to handle IO from the console, I assume there are also some to deal with the MIDI port.

Could someone tell me which functions they are, what parameters they have, and possibly give me a hint how to use them in personal Pascal?

Or is there a standard filename similar to "CON" that refers to the midi port?

Just some background info: I have a 520 ST with personal pascal version 1, and all I really want to do is play around with MIDI a bit.

2148. 520 ST power supply

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-30 02:17:44 UTC
From: jcksnsr@nmt.edu
Message-ID: <1991Apr30.021744.1728@nmt.edu>
Source record: 48477

Well, well, I was just typing along on my 520 ST this morning when crash, boom, incloud of noxious smoke my power supply fried.

Upon opening it I find two of the four rectifier diodes have gone to silicon heaven. Simply, a quick trip to Radio Shack and a little work with a soldering iron and the diodes are replaced.

No luck, I then find out that the primary coil of the transformer is now open and thus quite useless. (Mustof been some burn out, too bad the supply was under the desk where I couldn't see it.)

So I call around and discover the replacement is $65.00. About one sixth the total value of the computer, gack.

So the question comes down to this, 1) Does anyone know what the specs on the tranformer are and how it is wired so I can replace it myself (unlike the diodes the transformer is completely void of useful identifications) and 2) if not anyone know where to get a 520ST power supply cheaply and quickly.

I really wish I knew what happened, I'm assuming a surge since the computer is apparently unharmed and the fuse in the power supply is intact. But, if it was a surge, there was nothing happening today and it went through two surge protectors in the process.

Try the Bcon*() functions. (Bconin,Bconout,Bconstat,Bcostat).
function Bconin(handle:integer):char; (*read a character*)
procedure Bconout(handle:integer;ch:char); (*write a character*)
function Bconstat(handle:integer):boolean; (*checks input status*)
function Bcostat(handle:integer):boolean; (*checks output status*)

... those should be defined in whatever BIOS bindings Personal Pascal
uses.

To output a character, "Bconout(4,ch);" where 4 (i THINK) is the
handle to the MIDI port. If not that, it's three. (bad memory with
numbers and whatnot =:^))

Or to read one coming in, "ch:=Bconin(4);" should do ya.

... unfortunately, there isn't really any GEMDOS support for MIDI,
although i remember once reading about a standard handle "MID:". Not
very good, since you can't check for the existence of input data
without sitting and hanging the system until there is a byte received.
There's also a function in the XBIOS called
Midiws(count:integer;s:string); i believe it is, where count is the
number of characters of string to send, minus one.

Bad news for the blowing up of your power supply. $65 is rather cheap and you should buy it. The components are difficult to test because they are not isolated (think of dismantling all of them and test each of them -- will it be cheaper than $65?). As a preventive measure, I have replaced all the big capacitors with good ones. But anything can go wrong with all these penny-saving cheap machines. The transformer got burnt when the fuse is wrongly installed and some other wrong doing must have been there. The capacitors , resistors etc can be very expensive. Atari is very cheap and the companies are making profit. Just think of the real cost they can afford to spend for components: they have to be the cheapest parts in the world.

>Just think about bigsize == 320002...

Would you believe it? TWO forged messages in a row! The audacity of it!
And right after I changed my password to something no one would guess:
"password". (Oops! Now everyone knows!)

What the loser who posted that MEANT was:

#define CHUNK 32 /* or 64, 128, or whatever */

calloc((unsigned) (bigsize / CHUNK + 1), CHUNK);

You see here what the intruder was feebly trying to get at about "space
wastage" -- you get a few extra unused bytes at the end. Of course,
that's better than writing a few extra bytes _past_ the end, which is
what I think you were trying to get at with your picture. :-)

I hope whoever broke into my account saw your reply!

BIFF

uh, I mean

Why not just get a PC power supply? For example, Keypoint (12130 Mora Drive,
Santa Fe Springs, CA 90670, 213/944-3041) has a 150 watt XT supply for $36,
a 200 watt switching AT supply for $43, etc. That plus a line cord and
the appropriate shape DIN-7, and 12 hour with a soldering gun should put
you back into business.

Lots of folks sell such things. Look in Byte, PC Mag, PC Week, ...

2161. ICD SCSI adaptor

Newsgroup: comp.sys.atari.st.tech
Date: 1991-04-30 18:30:17 UTC
From: pyr579@oz.plymouth.edu
Message-ID: <1991Apr30.183017.14571@oz.plymouth.edu>
Source record: 48295

Hello,

I've been seeing all these messages on the ICD SCSI device and
I'm real interested in it. But I'm afraid I never saw the original
messages that told what it takes to do this. Obviously an ICS SCSI device
and a SCSI hard drive, but what about power supply and all the other
components to have an external drive? As far as I understand, a SCSI
hard drive only really means the hard drive itself, no external container
or power supply or controller (the ICD thing I guess). Can someone
who knows all the details send me info on this. I want to know all about
the whole thing, what are the limitations, how does the Atari recognize
the drive, etc.

Thanks,
Stephan

>Thanks in advance.

I, too, had this exact same problem. It seemed to alter the display memory because when I did a screen print it also had the lines and image shifting. I never did get a good feeling for what the cause was but found that lightly dropping the computer aggravated the symptom. I opened my computer and found nothing dramatic but pushed the chips back into their sockets and repackaged the computer. I haven't seen the problem repeat yet. The quad sockets used in the ST are pretty cheap quality and I wouldnt be surprised if they were indeed the problem.

Just thought I could add my $.02 in.

I had this problem about 3 years ago with my monochrome monitor.
After three trips to Atari to get it fixed (they kept claiming
that it was interference. Funny how it happened anywhere I took
it, and anywhere I put it), they finaly replaced the monitor
for me for free. I am not suggesting that they will always do this,
but since I never found out what the problem was, I would be
interested in knowing how it turns out.

>from mode 6 will be the return code from the process.

I should say that I'm working on a debugger (SZADB) which means I can't
just load-and-go.

I was trying to figure out how DB started a child process for debugging.
What I've divined so far with the aid of DB and SYSMON (and guessed) is
that DB does a load-and-go from its user stack but somehow manages to
convince GEM to trap on the first instruction and so re-enter DB in as
though a break point occured in the supervisor stack (which is not the
same as the usp). Later I assume, when the program terminates, it returns
from the Pexec() on the user stack and so receives the return code.

Provided the above is somewhat correct, how does DB forces GEMDOS to trap
on that first instruction by doing only a Load-and-Go (in a legal manner).

I suppose I could do the Pexec() Load-only, plant the breakpoint trap, then
do the Pexec() Go on the user stack, receive the trap on the super stack and
work in the debugger as normal. Later when the program terminates from the
Pexec() Go, I fall into the debugger on the user stack with the return code.

>>Q: What I want to know is the return code passed back in D0, on the

>The return code is not available at the terminate handler. The return
>code is the argument to Pterm() or Ptermres(), or zero for Pterm0().
>If you want, I guess you could catch those calls and squirrel away the
>return code before passing the call on to GEMDOS.

This one I figured out. It is possible to find the return code from the terminate handler. However I doubt I'll end up using this method.

```
terminate_handler:
move usp, a0 ;grab user's stack pointer
move.w 4(a0), d0 ;get GEMDOS function number
bnz.s .1
clr.w child_return ;Pterm0() - return code 0
rts
.1:
cmpi.w #$4c, d0 ;check for Pterm()
bne.s .2
move.w 6(a0), child_return ;grab the return code
.2:
rts
```

```
>I'm using now g++ and tried to use gdb for debugging, but there are no
>symbols in the programfiles. I read in a readme-file that I haveto use
>sym-ld for filling the prg-file with debugging info, but I dont know how
>to use it. Can someone give me a hint?
>Thanks in advance

From the gnu (.dvi :-) manual:

`-gg' Produce debugging information in GDB's own format. This requires
the GNUassembler and linker in order to work.

`sym-ld.ttp' is a special version of the linker. Its sole purpose is to
create a special symbol file used by the GNUdebugger. The following example
shows the usage.(`$' is the prompt of a CLI, `*' is the GDB prompt, `#' marks
a comment)

$ gcc -c -gg foo.c # compile `foo.c'
$ gcc -o foo.prg foo.o # linkwith normal `gcc-ld.ttp'
$ sym-ld -r -o foo.sym $(GNULIB)"crt0.o foo.o -lgnugdb (or -lgdb)
# link with `sym-ld.ttp' to get symbol file
$ gdb
* exec-file foo.prg # executable (`gcc-ld.ttp' linked Atari
executable)
* symbol-file foo.sym # symbols file (`sym-ld.ttp' `-r -o' linked)
* run
* <start doing gdb commands here>
: : :
* q
$ # back

Note the line in the example, where `sym-ld.ttp'is invoked. A library
`gnugdb.olb' is used to create the symbol file. This is just like the normal
library `gnu.olb' except that is was compiled.

Warwick.

>
> JEff

Although my original 520ST power supply hasn't failed, I replaced it
with a heavy duty (about 70W) Lambda power supply. Hooking up a
"generic" power supply isn't hard at all. The ST uses +12, -12, and
+5VDC, as well as a few grounds. All "IBM" type supplies, and many
of the "generic" power supplies have these voltages available. I just
bought the power connector at Radio Shack, grabbed some 6 or 7 conductor
wire I had, and hooked it up. Works great, and I never have to worry
about not having enough power for future expansions, or whether or not
the supply will last.

Since I use a "generic" floppy drive instead of an Atari drive, I also
power that off of the Lambda supply. I bought another supply for my
hard drive (70W isn't enough for everything), but two supplies is better
than a floor-full of black bricks.

I call appl_init when I start up.

/*
Here is the code that works fine when executed from the Laser C shell
but won't respond to the mouse buttons when run from the desktop
*/

int p_wait()
{
int ev_mmflags = 0x3; /* keyboard evnt & mouse evnt */
int ev_mbclicks = 1 | 256, ev_mbmask = 3, ev_mbstate = 0 ;
int ev_mm1flags = 0 ;
int ev_mm1x, ev_mm1y, ev_mm1height, ev_mm1width ;
int ev_mm2flags = 0, ev_mm2x, ev_mm2y, ev_mm2height, ev_mm2width ;
int ev_mtlocount, ev_mthicount, ev_mmox, ev_mmoy ;
int ev_mmobutton, ev_mmokstate, ev_mkreturn, ev_mbreturn ;
int ev_mmgpbuff[8] ;
int status ;
```

```
#ifdef DEBUG_P_WAIT
printf("calling evnt_multi, Numahead = %d\n", Numahead) ;
#endif

/*
No it's not returning here when run from the desktop. I have
to strike a key to get it to return
*/
if( Numahead > 0 )
return P_KEY ;

status = evnt_multi( ev_mmflags, ev_mbclicks, ev_mbmask,
ev_mbstate, ev_mm1flags, ev_mm1x, ev_mm1y,
ev_mm1width, ev_mm1height, ev_mm2flags,
ev_mm2x, ev_mm2y, ev_mm2width, ev_mm2height,
ev_mmgpbuff, ev_mtlocount, ev_mthicount,
&ev_mmox, &ev_mmoy, &ev_mmobutton, &ev_mmokstate,
&ev_mkreturn, &ev_mbreturn ) ;

#ifdef DEBUG_P_WAIT
printf("evnt_multi status: 0x%x\n", status ) ;
#endif

if( status & 0x2 )
return P_MOUSE ;
else if( status & 0x1 )
{
/*

stuff keyboard entry into console input buffer
*/
#ifdef DEBUG_P_WAIT
printf("ev_mkreturn = %c (0x%2.2x)\n", ev_mkreturn, ev_mkreturn) ;
#endif
Nextinchars[Numahead++] = ev_mkreturn ;
return P_KEY ;
}
/*
shouldn't get here
*/
return P_KEY ;
}
```

When I run from the desktop with my debug statements turned on, I don't get a return and status from evnt_multi until I use the keyboard. The setting of the high bit in mb_clicks is not the cause. Giving it a mask for the left mouse button without the logical negation, the simplest case, it still has the same problem. I have hardly run the program outside of Laser c, but I think it was working from the desktop previously.

Any ideas?

Mike Healy

2174. AHDI in auto folder: no auto PRG's executed

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-01 08:38:42 UTC
From: dick@ahds.UUCP
Message-ID: <1982@ahds.UUCP>
Source record: 48309

A while ago I posted this cry for help about the fact that when I placed AHDI.PRG as the first program in the AUTO folder, no other programs which were placed there were executed.
The problem has been solved. Thanks to all people who responded !
A summary of the solutions follow:

I placed AHDI.prg in the AUTO folder of the harddisk. The reason I did that, was that the manual was not very clear about the subject and I didn't read it exactly to the letter. Reading mail of several people who responded, I am not the only one!

Well, AHDI should NOT be placed on the AUTO folder. The driver.sys file in the root directory is the real driver and includes AHDI. The AHDI.prg program is solely needed to place on FLOPPIES if you want harddrive support, but boot from a floppy.
So, when I removed AHDI.prg from the AUTO folder, all problems vanished.

The reason that the problem evcer occured is, that AHDI, when ececuted in an AUTO folder, re-initialises GEM, so all other programs in this folder will NOT be executed.

Thanks to all of you who responded. You were a wonderful audience.

Dick.

or

for(i=0;i<16;++i)
Setcolor(i,0);

But this will never blank a mono monitor - with color it will do.

Be sure to restore the old color values, get them with old=Setcolor(x,-1);

From article <2913@atari.UUCP>, by apratt@atari.UUCP (Allan Pratt):
> Humph. TOS 1.4 and upwards have NO PROBLEMS with Malloc that have been
> reported to me.

Hmm, try Malloc'ing little blocks until the OS returns NULL because there
is no internal memory left for the MD's.
Then Fopen() something.
I think Fopen should return -39, but it will blow up the 'OUT OF' message.

There are still other problems:
Fdup'ing an already Fdup'ed handle causes the 'OUT OF' too.

I just mailed you (Allan) a better description including sample source.
If you don't get it via e-mail, please let me know.

Greetings, Bjoern

2177. How to Mshrink a C program ?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-01 13:00:46 UTC
From: gerardio@boffrand.crin.fr
Message-ID: <3702@loria.crin.fr>
Source record: 48307

I'm writing a program using Lattice C (v3.03) on a 1040 STF, and from within this program I want to run an external .PRG program via the Pexec function.
Unfortunately, it works fine only when the program I call needs not too much memory.
I know where the problem is: my program owns (almost) the whole available memory, leaving only a few Kbytes for Malloc's !!! But how to get my program to Mshrink to the size I want ?

Thanks in advance

Olivier

2178. fitting a hard disk

Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I'm posting this for a friend who has no access to the news or
mail. I will pass on any replies.

Hello there

I have and Atari STE and want to attach a hard disk to it. I
have also been given a surplus hard disk by my employers. The hard disk
is marked

"RODIME R0351 type 2"

Is there any way I can attach this disk to the machine directly ?, via a
controller of some sort ?, which controller type ?, where can I get one
from (In the UK) ?. If this disk isn't suitable can anybody suggest a
(cheap,reliable) type that is and tell me what I need to do to attach it
to the machine.

Rather a lot of questions I know but I am *DESPERATE* for a hard disk.

Please bear in mind that I am not very technically minded and am
relatively new to computing and computers. Please can you reply to my
friend at j.a.jones@lut.ac.uk .

Cheers
Steve

2179. Help with timerA

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-01 14:43:21 UTC
From: tsakogia@uk.ac.man.cs
Message-ID: <TSAKOGIA.91May1154321@r6.uk.ac.man.cs>
Source record: 48323

This message is sent on behalf of Pakis Haliapas (haliapap@p4.cs.man.ac.uk):

* *

Does anybody out there know why when I compile the following program
(with HiSoft's GenST assembler) and run it on my STE the system crashes?

```
-------------------------
start
bra real_start
even

TimerA_int
rte
even

real_start
clr.l -(sp)
move.w #$20,-(sp)
trap #1
addq.l #6,sp
move.l d0,old_sp

move.l #TimerA_int,$134
move.b #128,$FFFA1F
or.b #$07,$FFFA19
or.b #$20,$FFFA07
or.b #$20,$FFFA13

move.l old_sp,-(sp)
move.w #$20,-(sp)
trap #1
addq.l #6,sp

loop1
move.w #2,-(sp)
move.w #1,-(sp)
trap #13
addq.l #4,sp
cmp.w #-1,d0
bne loop1

move.w #2,-(sp)
move.w #2,-(sp)
trap #13
addq.l #4,sp
```

```
clr.w -(sp)
trap #1

cl_counter dc.l 0
old_sp dc.l 0
-------------------------
```

The following program does exactly the same thing too:

```
-------------------------
start
bra real_start
even

TimerA_int
rte
even

real_start
move.l #TimerA_int,-(sp)
move.w #128,-(sp)
move.w #7,-(sp)
move.w #0,-(sp)
move.w #31,-(sp)
trap #14
add.l #12,sp

loop1
move.w #2,-(sp)
move.w #1,-(sp)
trap #13
addq.l #4,sp
cmp.w #-1,d0
bne loop1

move.w #2,-(sp)
move.w #2,-(sp)
trap #13
addq.l #4,sp

clr.w -(sp)
trap #1

cl_counter dc.l 0
old_sp dc.l 0
-------------------------
```

Send any answers/comments/suggestions to

2180. Re: GDB question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-01 15:06:44 UTC
From: timothyg@ncsa.uiuc.edu
Message-ID: <1991May1.150644.11919@ux1.cso.uiuc.edu>
Source record: 48312

[in response to a question about how to use the gnu debugger]

```
|> $ gcc -c -gg foo.c # compile `foo.c'
|> $ gcc -o foo.prg foo.o # linkwith normal `gcc-ld.ttp'
|> $ sym-ld -r -o foo.sym $(GNULIB)"crt0.o foo.o -lgnugdb (or -lgdb)
|> # link with `sym-ld.ttp' to get symbol file
|> $ gdb
|> * exec-file foo.prg # executable (`gcc-ld.ttp' linked Atari
|> executable)
|> * symbol-file foo.sym # symbols file (`sym-ld.ttp' `-r -o' linked)
|> * run
|> * <start doing gdb commands here>
|> : : :
|> * q
|> $ # back
|>
```

Well, that is what the instructions say. When I follow this procedure, I get bombs after 'symbol-file foo.sym'. I have yet to hear from anyone who has been able to get gdb to work. I have heard from several people who cannot. Good Luck!

Can anyone help the poor souls who are without a debugger?

>2 chips, which EPROM type do I need?

I found the same thing when I upgraded my Mega-4 to TOS 1.4 -- six sockets, the old ROM was on two chips and the new on six. Instructions that came with the new ROM told how to make the conversion. It involved removing a soldered-in chip and changing a jumper. I had my dealer do the work. He tried unsoldering the chip instead of simply clipping the pins and damaged the motherboard in the process. He finally patched things up and got it working, but I would never do it again unless there were absolutely no alternative.

My recommendation: Take back the 6-chip TOS 1.4 ROM set and get the 2-chip set instead. Then you just plug them in in place of the old chips.

When I replied to your posting, I didn't notice that you were talking
about "EPROMS with TOS 1.4". I know that Atari distributed early
copies of TOS 1.4 on EPROMS but later switched to ordinary ROMS. I do
not know if TOS 1.4 is legally available any more on EPROMS, but if
the EPROMS that you have are not legal copies, then I do not condone
what you are doing.

evnt_multi does many things, and it even seems to buffer keyboard
events in some manner. Moreover, it's just the recommended method
for sampling the keyboard when using AES functions. Internally,
the AES calls the VDI, and the VDI probably calls BIOS, but nobody
knows exactly what else goes on.

>drives are out there.

No, both the Supra and the ICD will allow for the absence of a SCSI device
number 0 (ie they both support muliple devices).

>As for the ST/TT side of the bus, you have to start with zero on each bus
>and increment by one for each drive you connect to that bus. (Remember,
>that's unit numbers as the computer sees them, not as the adaptor sees the
>disk it's actually talking to.) The reasons for this are kind of involved,
>and I don't want to go into them; just take my word for it and carry on.
>

The reasons for this have always been the exact question which I have been
asking. At this point, an explination does not interest me. However, I
do think it would be rather nice if a paragraph or two was included in the
TT manual explaining this phenomena, and how to correct it with a few of
the major brands of host adaptors. The DMA port on the back of the TT
is handled differently than that on the various ST's, and this could cause

an hard drive set up (and working) on an ST to fail (with very little
explanation from the Atari HD software).

>I have even heard of some adaptors which look at the SCSI unit number of
>the drive that's connected, and configure themselves as that ACSI unit
>number, further confusing the issue.
>

This is very likely the reason why the drive did not work. Since the
SCSI disk was set to ID 1, perhaps it set the ASCI number to the same
(thus confusing the Atari HD software). It would be interesting to
see if the BMS and ICD host adaptors create the same problem.

2187. GDOS with a Hard disc

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-01 22:49:26 UTC
From: swanee@megadata.mega.oz.au
Message-ID: <1991May1.224926.22878@megadata.mega.oz.au>
Source record: 48320
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Well here I am trying to run the Analyze spreadsheet from my hard disc, firstly trying to load GDOS (V1.1) in order to print out some graphs. But alas, when trying to run GDOS with the hard disc (Supra adaptor and S/W) GDOS falls over in a crumpled heap. The whole thing works OK from a floppy disc though. Do I have a pre-cambrian version of GDOS which is incompatible with the hard disc S/W? If so, which version is recommended and from where should I procure it?

Thanks in advance,
Geoff Swan.

2188. Re: DBMan Programming question (ALSO Lattice gripes)

Newsgroup: comp.sys.atari.st.tech

swood@vela.acs.oakland.edu (EVENSONG) writes:

>I am about to delve into the world of DBman and DataBase III+ style programming

I happen to have written a lot of the code in dBMAN (especially the
Amiga and Atari versions) so I can surely help.

>I am hoping to be able to do a search of a couple of various feilds in my
>database.
>a finished string might look like : 'AB?D?F?H??KLM?O???ST??WX?Z'
>I am going to be writing a program then to find the closest match(es)

Well the dBMAN (and dBASE) way of doing this would be to write a
UDF (or procedure) that scans two strings, character by character, and sums
up how close they are. Then you simply scan the database a record at a time
to find the closest record. Rather simple.

Speaking of dBMAN, I can't release the latest version for the Atari until
there is a compiler that supports the 68030! (we have only a TT030 for
development) Mark Williams compiles, but has no debugger (well, it has
a crude monitor that doesn't run on the TT anyway) and recently
decided not to support the Atari at all. Lattice also compiles, but the
executable won't run with a 68030 and the debugger doesn't support the
030 either. Lattice (Hisoft, actually) does have a 68030 version - but they
want developers to pay $300 MORE just to BETA-TEST it. Sheesh!

This (incompatiblity of existing software with the latest hardware)
is kind of sad compared to the Amiga... we use a 4-year old compiler
on our Amiga 3000, which runs perfectly (even the source-level debugger)
and creates trouble-free executables. I assume this is because the OS
was intended to gracefully scale upwards, unlike the Atari. Perhaps the
developers just ignored or lacked a set of compatibility guidelines.

There is source code at panarthea which alters GEM metafiles produced by Uniterm to those readable by Easydraw and Calamus. The file is called EZGEM I believe.

This should offer clues to solving your problem (I only had time to scan the docs this morning, it seems that the file addresses the sizing information problem).

Best Regards,
Mark Onyschuk

These soundfiles contain 8-bit-sampled sounds with 0 as the lowest an 255 as th
e highest value. To play such a sound, you "only" have to use the internal
soundship as a D/A-converter. To do so, set all the delay-values in the registe
rs 0 to 5 of the soundship to 0 (the highest frequency it can play) an then
turn it off (it has really to be off, otherwise there are interferences in the
sound). Install then an interrupt-routine that gets every time it's called a
byte from the soundfile (which hab been read somewhere into memory), then
converts it with a table, because the soundship has only 4 levelcontrolbits
per voice and it's not linear. You can get this table by analysing one off
those soundplayers while playing a sound, they often use the timer-a-interrupt.
There you can also see a playing routine. After converting, all you have to do,
is put the 3 values for the 3 voices into the right registers (I think it's
8 to 11)

When using the DMA-sound of the STE, remember that these sounds range from
-128 to 127 (signed), so you have to convert them before playing.

Whilst on the subject of printer drivers in general, could someone post
details of the 'printer.sys' file most commonly found referred to in the 'assign.sys' with
driver ID 21 ? I have a printer which emulates an Epson, but most
Epson drivers do not use the quadruple density graphics mode which my printer
has. I have tried hacking the printer.sys file... I can get the printer into the
correct mode, but the driver only sends enough data for 960 dots per inch,
whilst I want 1920. A posting of this files structure would be of great help
to me - output from timeworks is really horrible, I'm sure my printer can do better.

>Does anybody have any experience porting programs built on the X11
>model of client-server programs to GEM (or anything else) on the ST ?
>(I know..... I COULD wait until I could afford a TT and *nix..)

This is not as difficult as it seems. The other way around is a lot more difficult!

What you have to do is:
0) When initialising the program register all client functions
(You want to get a pointer to them).
1) make a endless loop in your program
2) put in there an event_multi and a (huge) switch statement
3) at all switch labels, see iff there is a client, and do him or if there is no client, do the default.

Here is an example of untested pseudo code:

```
register_clients();
while(1)
{
event_multi( all options enabled );
switch( type off message )
case keyevent:
find_active_window();
if (there_is_a_client(window))
(*do_client_function( window, key );
else
do_default_key_action(window);
break;
case mousevent:
...
...
}
```

I assume you mean, "Is there a way to change resolution such that GEM, AES, and VDI calls will work in the new resolutuion?" If so, the answer is no. Absolutely, positively do NOT bother trying to find a way to do this. It's completely impossible to accomplish without relying on undocumented locations in the ROM.

>Also, is there any way to force a resolution change WITHOUT a resulting
>reboot of the system. I mean, from desktop (med) to desktop (low) and vice-versa?

Find out that, and you can also switch to hi-resolution without rebooting too.

It can easily be done, but letting AES know is the problem (as you doubtlessly
realise). When I write low res games, I write them on the mono-monitor,
and just switch to the colour monitor to run them. All you have to do
is set the trap vector for it to your own routine.

You can force the mouse to be bounded correctly by re-initialising it (XBIOS).

The problem does remain, how the get the AES to work properly. There are
about a half dozen places in memory that have "640,400" or "639,399" stored,
so there is probably no central, legal way to slap AES in the face to wake
it up to a change in res. Ah well.

Warwick.

2197. SCSI chip project

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-03 08:02:06 UTC
From: kiki@uhunix1.uhcc.Hawaii.Edu
Message-ID: <12824@uhccux.uhcc.Hawaii.Edu>
Source record: 48335

A lot of current discussion concerns the SCSI and a floppy chip replacement, so this probably unoriginal thought occurred to me: replace the WD 1772 chip with an NCR 5380 SCSI chip. I would agree with an attempt at a floppy chip upgrade if SCSI floppy drives were unavailable, but it seems that the logical and physical interface space should be used for an ANSI standard SCSI port.

I managed to get an ST Internals book and it appears that the WD 1772 chip can be replaced with an NCR 5380 SCSI chip. The 5380 has 40 pins so an adaptor board is necessary, but it requires almost no support chips. I think it needs a buffer on the data lines from the DMA chip, because TOS will bootup and think it's configuring a WD 1772. Also, it has three address lines to select among its eight registers, so a free sound chip port bit needs to be connected, but replacing the floppy chip also frees up a couple of port bits that are used for drive and head selection. DMA control lines have to be connected, but I don't have enough info on either the 5380 or the ST DMA chips.

If anyone has suggestions about this possible project, please let loose your ideas. Also, I read that Sybex has published a new 1300 page book about the STE/TT computers, but their US sales office claims that it doesn't exist. It may have been written by European authors, so if anyone there can furnish me with its ISBN, I would be very happy.

Thanks,
Jack

2198. AT emulators, general + specific questions

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-03 09:52:30 UTC
From: jensting@diku.dk
Message-ID: <1991May3.095230.20449@odin.diku.dk>
Source record: 48334

Having installed the c't external keyboard (AT keyboard into MIDI port), and
being interested in buying an AT emulator (for programming, not for use ;-),
I need to know if the available AT emulators (ATSpeed(+), ATOnce,
PC-speed with 286 extension(?)) will accept the external keyboard.

The external keyboard works by jumping into the middle of the keyboard
interrupt handler (found by finding a specific cmp -- bra combination,
ugh!) from the MIDI interrupt routine. (Oh boy). So, for the AT emulators
to use this thingy succesfully they need to use the original keyboard input
routines (i.e. NOT changing the interrupt vectors, just the BIOS handlers).
I would appreciate any light you netlanders could shed on this.

Also, what is the opinion on the general performance of the AT emulators?
how is the service (say, in Germany, I live in
London and speak Germen)

how is the software compatability (extended - expanded memory
etc) ?

how well do they cooperate with ICD harddisks?

Many thanks for any and all info.

2202. Mega bus specification request

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-03 16:05:16 UTC
From: michael@dime.cs.umass.edu
Message-ID: <30049@dime.cs.umass.edu>
Source record: 48338
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have a working PC-Ditto II that I used to use with a 1040ST, but now I have a Mega 2 that has one of those tiny circuit boards soldered onto the 68000, and can't fit the PC-Ditto II adaptor board over it.

I would REALLY RATHER NOT take a soldering iron to my motherboard, especially to the cpu, so I was wondering how feasible it would be to build some sort of adaptor cable to plug into the Mega bus. Could someone post the specifications for a Mega bus? I notice that it has the same number of pins as the 68000; are they the same lines, and if so, how are they mapped?

I've seen ads for Mega bus adaptors for PC/AT Speed, and the two prices I've seen have been $65 and $79, which leads me to believe that it isn't just a simple line by line adaptor. Does anyone have one of these, and if so, could you describe it?

I'm not willing to damage my computer just to be able to use this thing again, but if I can get it attached without too much difficulty, I'd like to know.

Thanks in advance for any information you have to offer.

Michael Kieras

2204. Exabyte 8mm tape drive and TT030

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-03 16:55:27 UTC
From: vspicer@ccu.umanitoba.ca
Message-ID: <1991May3.165527.29560@ccu.umanitoba.ca>
Source record: 48340

I am currently attempting to get our TT030 to talk to an exabyte EXB8200
tape drive through the TT's SCSI port. Does anyone have code for communicating
with the SCSI port? I've gone through the manufactuer's data sheet on the
5380 SCSI controller chip, and it's registers are mapped into TT addressable
memory ($8780-$878E).
The new Xbios call 0x2a/0x2b (DMA read/write) don't do anything; the routine
returns a -1 error code. It was a long shot anyway, since it deals in
"sectors" (hard disk devices only, i guess). Even the address for where
this particular call is located would give me a place to start.

thanks in advance
vic spicer

It bothers me that you're recommending that someone disassemble my code and use it verbatim. Whether or not this is legal, I have no idea, but please note that play.prg is COPYRIGHTED, although it's freeware. It's NOT public domain. This is the sort of thing that makes people not release their software as shareware at all, especially considering that only a handful of people every attach the programmer's name to the "gift" in references like the above.

For the record, I've gotten many requests for my sample playing source code, and I regret that I can't give it out because it's for a commercial product. In the past I have given detailed explanations of how to play digitized sound on the ST, posted here. I don't have time to do it again at the moment, unfortunately.

Instead of disassembling play.prg, please look for resound.arc on atari.archive. If it's not already there, I'll put it there. It's by David Snow and implements the same techniques my routines do. Source is included in the arc file.

I don't mean to flame you, Warwick. On the contrary, I'm glad you post here -- your articles are quite helpful. But consider how you'd feel if I disassembled STrabble and used your dictionary without your permission.

>explanation from the Atari HD software).

A phrase like "The DMA port on the back of the TT" encourages misunderstanding: there are TWO DMA ports on the back of the TT; one is ACSI and one is SCSI, and you should make that distinction explicit when you talk about the TT.

In any case, you are mistaken. A working setup on an ST will work fine on a TT. What part of this conversation makes you think it won't? The only oddity will be that SCSI drives (like the internal one), if present, will have their partitions appear first in the sequence of drive letters. But if you have a working chain of drives coming out of your ST, and you unplug the end of the chain from the ST and plug it into the TT, all those drives will be accessible and will work just fine.

In article <aV2911w164w@sys6626.bison.mb.ca>, marco@sys6626.bison.mb.ca (Marco) writes:
>I have been considering buying Spectre, but I have a few questions.
>First, what's the difference between GCR and 128?

The 128 gives you a Mac, but with a non-standard floppy drive. You will have to transfer all of your Mac software via modem or direct-connect. This is because the Mac's use a strange floppy protocol that cannot be emulated on the ST without additional hardware.

The GCR (stands for Group Coded Record, which is the name for the strange floppy protocol) provided the additional hardware noted above. Thus, your ST floppy drive(s) will be Mac compatible. Therefore, the GCR is a more complete emulator than the 128 (only in terms of the floppy, they are equal in ability to run Mac stuff). Also, any protected software would require a GCR to work (games).

>What are "Mac Roms" and why would you want them?

A small explination of the Spectre is in order. The Spectre is a software program that takes an ST and a copy of the Mac OS and yields a Mac compatible. Now, for Mr. Small to be able to do this, a copy of the Mac OS is needed. That is what is contain on the Mac ROMs. The Spectre is sold as with a cartridge that accepts the Mac ROMS and plugs into your ST. This is the only legal (in terms of Apple) way of providing the Mac OS. Dave Small cannot sell Mac ROMS. In other words, you need the Mac ROMs to get around legal, not physical or practical rules. There have been pirate copies of the Spectre (128) that provide the Mac OS as a file on the disk (with no hardware needed).

>Is Spectre 100% Mac compatible?

It is about 99.999%. Most Mac's are not 100% Mac compatible :-) .
Dave Small upgrades his stuff constantly, and updates are free.

Mac ROMs are getting hard to find, as Apple has changed it's policy on selling them (apparently they were getting worried about Mac clones or something). I would secure a set of 128k Mac ROMS first, before buying either of the Spectres.

I would recommend you get a GCR, since Mac software will be usable right out of the box.

If you run into any of the pirated software-only versions of the Spectre 128, please do not use them. Dave Small has done some incredible things for the ST, and is currently working on some REALLY promising stuff. It would be a shame to see him go (as have so many other great ST programmers, like Tom Hudson). Either Spectre is cheap for what you are getting. Also, these pirated versions are heavily hacked (Mr. Small's code to check if the OS is

in ROM has been removed from many places) and totally unreliable.

2208. ATARI Monitors for Sale

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-03 18:45:14 UTC
From: smisra@eos.ncsu.edu
Message-ID: <1991May3.184514.21533@ncsu.edu>
Source record: 48333
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I would like to sell an ATARI Color Monitor SC1224.

I am upgrading to an IBM system, and since there is no
way that I know of to be able to use (cost effectively)
this color monitor with a PC Compatible, I have no further
use for it. Also available is an ATARI Monochrome Monitor
SM124. Only one will be sold (I still want to be able to use
my ATARI)

Prices will be competitive!!

Please reply via email.

(BTW: If anyone knows a cost effective way to use my ATARI SC1224
with a PC using a video card like CGA, please let me know. Also
does anyone know what the dot pitch is of this monitor .51 ??)

Thanks
Saurabh

>controller or SCSI controller. Do you think ATARI will listen to us?
>I am not so sure that USENET reflects the opinions of the vast majority of
>users (games or music people).

This project would be primarily for people who don't have the Mega STe/TT, because Atari supposedly will provide some type of floppy upgrade kit for the Mega STe and TT owners. That leaves several million ST owners who probably want a HD or VHD drive, with the alternative of the Dreampark floppy kit you cited in another post, or an embedded-SCSI floppy with a SCSI adaptor.

I can think of these advantages to my proposal:

1) Following ANSI specs will allow connection to peripherals 18 ft. (6 m) away.
2) Enhanced reliability because of ANSI conformance
3) Low chip count, compared to commercial SCSI adaptors.
4) Internal design
5) Cheap (~$10 for NCR 5380 and ~$20 for other parts)

Some disadvantages:

1) Like Dreampark kit, requires desoldering floppy chip
2) Requires wire wrap equipment (~$10)
3) Interfacing to TOS may be difficult.
4) Case must be modified to install a connector

The hardware part appears to be straightforward, but TOS will be a little confused! If anyone has any ideas about adapting it to TOS, please let me know.

For most people, the ICD SCSI adaptor would be a good alternative, but for people using their ST's with numerous peripherals which are constrained by the electrical limitations of the DMA port, this project may be a practical solution. The combination of the ICD SCSI and the NCR chip SCSI would make the ST a pretty formidable machine.

Jack

I have been considering buying Spectre, but I have a few questions.
First, what's the difference between GCR and 128?
What are "Mac Roms" and why would you want them?
Is Spectre 100% Mac compatible?
If anyone could answer any of thse questions it would be greatly
appreciated. Thanks.

The GCR allows you to read and writes MAC DISKS, the 128 Cart doesn't
allows this.

You need the Mac ROMS to run the Emulator period. No ROMS No Emulation.
(If you can find MAC ROMS UNDER $300, YOUR LUCKY, I question now whether
or not this is a good approach anymore as a Classic is pretty cheapo
and you can RUN ANYTHING)

Its pretty close to 100%, but mainly cannot run games.

On a further comment. Currently there aren't any GCR's to be had anywhere.
I suspect Mr. Small is getting out of that market as ROM prices are making the
Mac option on the ST pretty rediculous, which is a smart move.
Hopefully after he dumps the emulator he can work on his 030 board full time,
which I think is more important anyway.

I have a set of ROMS if anyone wants them, for $500 bucks, brand new. :)

Let me know if you are interested.

From article <1885@qusunb.queensu.CA>, by driesse@qucis.queensu.CA (Anthonie Driesse):
> Since there are GEMDOS functions to handle IO from the console, I assume
> there are also some to deal with the MIDI port.

No there aren't since MIDI is a device GEMDOS doesn't know about.

> Or is there a standard filename similar to "CON" that refers to the midi
> port?

Nope.

XBIOS / BIOS give you some:

Bconin/Bconout/Bconstat/Bcostat work on BIOS device 3.

All TOS versions I know swap Bconstat/Bcostat on dev 3.
Atari states that this will be maintained for compability.

Midiws(count,ptr)

Writes count+1 bytes from ptr to MIDI.

Beware in Pascal: ptr has to be a real char array, not a pascal string.

> ST.

If the docs aren't posted in the archives, I've got them. The modification is fairly simple really. I'm about the -last- person you'd let near your motherboard and yet, my installation went like a charm. (Of course it took me a little longer than most people's estimate of 10 mins)

Frankly though, it really hasn't been very useful for me (I installed it 24 hours ago) Not a lot that I use works in overscan mode. Laser C's editor doesn't work, some aspects of NeoDesk don't work (show file from desktop, screen blanker), GFA Basic doesn't work, Tempus II doesn't work, Quick ST V2.21 doesn't work and the list just keeps on going.

>drives when they buy the cheapest ATARI ST very soon. No worry, I hope.

This sounds reasonable. I wonder how much of a supply of WD 1772 chips
does Atari have left? Also, how much did it cost to reverse-engineer the
1772 chip? Was doing that cheaper than a board redesign with a chip like
the FDC 92C36 you recommend? Who is responsible for these decisions?

>I have experience of using NCR53C80, but it is not particularly remarkable.
>It is just one of the SCSI chips. It will be a good idea to abandon the
>traditional DMA interface and accommodate only a MAC style SCSI port,
>urging people to buy MAC peripherals. But I would think a floppy disk
>controller will be still useful especially because OS needs no fix.

I don't have any SCSI experience, but one thing I noticed in reviews of
peripherals using the ST ASCI (and Mac SCSI) port is that they are severely
limited by the short cable length brought on by not following ANSI SCSI
specs. I think ST owners want to be able to connect hard drives, PCs with
SCSI, A/D D/A converters, etc. at a physical distance that is convenient to
them, not their ST.

I am beginning to become more convinced that the OS should not be in rom,
but on a JEIDA standard ramcard. They are available in 4 MB capacity and
a 12 MB ramcard will be out soon. Since JEIDA specs allow ramcards up to
64 MB, Atari Unix may eventually be distributed on these things. Performing
OS updates would just mean downloading some code either from an Atari or local
dealer's BBS. Since the new ST Notebook is using them, I am hopeful Atari
will put JEIDA sockets on future lines of desktop STs.

One idea that I have for older STs is a JEIDA ramcard drive connected to
the ASCI-SCSI bus. TOS would be patched to load in an OS stored on a ram-
card. The drive would have extra sockets so that you can have hundreds of
megabytes online.

>I have one internal 3.5" and one external 5" drive, both of which cope
>with normal density and high density. What has been most impressive is
>that I have never required any software to make use of this. Even Minix
>has been very happy with them.

If you are satisfied with your present arrangement, then that is great, but
I just want to investigate another option. Floppy controllers can only con-
trol floppy (or tape) drives; the SCSI controller provides hardware general-
ization that blends nicely with the software paradigm of data abstraction.

But the SCSI flexibility is crippled when manufacturers take shortcuts in implementing the standard and I believe most people would like to utilize their systems to its full potential.

>90 degrees and soldered together and connected to a switch from either
>+5V or GND.

Rather than bending the pins, it must be simpler to cut the PCB traces to
pin 1 of the 28-pin sockets. This only works for a 6-chip ROMset. IMHO it is
better to make a change that requires the soldering iron to be wielded once
instead of every next time the chips might need changing.
The same idea of an upper and lower bank could be used to make a 2-chip set
on 2-Mbit EPROMS containing 2 different versions (only works on 32-pin sockets).
Another possibility is to use 2 or 3 different 2-chip ROMsets, one in each
pair of sockets. This would appear to be the most common and simplest solution.

On the other hand, I believe there is a disk-bootable version of TOS 1.0
which is legal to run on any Atari ST. If TOS 1.2 is not needed and memory
large enough, this might be the way to go.

Source record: 48257

hello,

i'm trying to write a sort of texfile-displayer for my st. i would like to replace the standard displayer (show-print-cancel-alert box from the desktop) but this seems a little too ambitious to me. i have thought of one alternative, and that is to write an accessory which displays all the selected files from the desktop (i prefer this over a file-select box).

does anybody know if there is a place in memory where the st keeps the names of the selected files, the abstract data structure they are kept in and (probably most important): if this place is 'official' (i.e.: is this place guaranteed for *all* TOS versions?)

if this is not known or not guaranteed,does anybody know how to replace the standard 'more'? is it just a vector in RAM or is it put in ROM?

thanx in advance,

From: optimiza@utrcu1.UUCP
Message-ID: <832@utrcu1.UUCP>
Source record: 48258

Another question about DBMan: Is it possible to send a NUL byte to a
(serial, MIDI)-port? I have tried this in a number of ways, and it looks
as if DBMan treats all things to be sent to ports as C strings, so the
NUL is seen as a terminating character, and never transmitted.

>you talk about the TT.

Implicitly I am referring to the one which also exists on ST systems, which is
the ASCI one. Are you telling me to be more up to snuff on my technical
descriptions? Crack open an ST or TT manual sometime, and get your red
pen out . . . .

>
>In any case, you are mistaken. A working setup on an ST will work fine on

>if you have a working chain of drives coming out of your ST, and you unplug
>the end of the chain from the ST and plug it into the TT, all those drives
>will be accessible and will work just fine.
>

Wrong.

<sigh> Here we go. Ok Allan, here is exactly what happened (for the third
time :-).

A working ST system: Mega4, laser printer, Supra Hard disk. The SCSI
drive contained within the Supra is set to SCSI id 1. The ST does
not mind this at all. Everything works.

A TT system is purchased.

The DMA cable connecting the Supra to the working ST setup is disconnected,
and attached to the ASCI DMA port on the TT.

The computer is booted.

The Supra is invisible to the TT desktop, for no apparent reason. Nothing
is stated in the manual. No error messages from the HDX software.

What was really strange is that the Atari formatting software could see the Supra (and it was later used to format and partition it, to no avail). However, nothing could make those partitions show up in a window on the desktop. This was finally fixed by tearing the Supra apart and setting the SCSI disk contained within to SCSI id 0.

The question WAS: why did this have to be done? It worked fine on the ST when set to SCSI id 1.

Please do not answer this question. I don't care anymore. Nobody cares anymore. All of us that read all this bandwidth will carry the "set it to zero and try it" solution for the rest of our days. We will repeatedly tell new TT owners this when they post the "what the hell is wrong with my hard disk" question on c.s.a.st. This will just become one more such tidbit of information that is needed to have success with ST/TT's, and is not printed in the manuals that come with the computer(s).

2225. gnu emacs and TERM

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-05 17:16:57 UTC
From: lynbech@daimi.aau.dk
Message-ID: <1991May5.171657.6543@daimi.aau.dk>
Source record: 48260

In order to get the function-keys to work on my atari under emacs, I have been experimenting with setting up a vt52.el file so that keypad.el would run. This may not be the easiest solution, but it is standard to the way emacs handles terminal specific things.

I managed to get the file together, but I can't emacs to load it automatically. The problem appear to be that (getenv "TERM") always returns "vt52-emulator", REGARDLESS of the real value of TERM. I have tried this, both with environ.prg and under gulam, but no matter what TERM is set to, (getenv "TERM") still returns "vt52-emulator". All the other environment variables works fine however.

Why is this? My suspicion is that it has something to do with a termcap hack. My version (which I think comes from atari.archive, at least the st hacks bears Bammi's name) doesn't need the termcap, so perhaps something has been hardcoded into emacs.

Hi JC,
You asked about attaching a PC-type keyboard to your 520ST.
Personally I would recommend using the DEKA from WuzTEK. It lets you
connect any XT/AT PC keyboard to any ST/STe/TT machines. It has BarCode
scanner support. It also has Mouse/Joystick ports. And most importantly....
it requires NO software! Just plug it in and it works.
In case you need the phone number; it is, 714/753-9253. Bye.......

Luis

P.S. Nope, I don't work for WuzTEK; I'm just aware of the product.

Message-ID: <1991May6.023631.1912@ux1.cso.uiuc.edu>
Source record: 48267

I have been trying to figure out how to get the address
of an object in a tree using rsrc_gaddr() without any success.
The problem is that I have 2 trees, and in each tree several objects.
I can't seem to get the address of object 1 from tree 0 and object 1
from tree 1- I get the same address (obj. 1 from tree 0) for both
of them. Is there some way to have the rsrc_gaddr distinguish the
2 objects from one another? The Turbo C manual warns that there can
be problems getting pointers to anything other than trees, but the
explaination that you should get a pointer to the tree and then get
pointers using this root pointer doesn't seem to work since I can't
get the pointers to the children (I can't see how, anyway).

If anyone has had this problem and figured it out, please
let me know what the solution was. I need to be able to get the results
from multiple editable text fields and am really stumped.

Thanks in advance,

Michael Stepniczka

Source record: 48273

(note: the following code is what I recieved when I asked a similar question..)
(i think its by wolfgang.... i left the name at the bottom)

```
terminal()
{
int c;
long w;
for(;;)
{
c=Bconin(1); /* read from aux */
Cconout(c); /* output read char */
if (Cconis()) /* only if key was pressed */
{
w=Cnecin(); /* read from con */
if ((w>>16)==EXIT)
break; /* terminal exit condition */
Bconout(1,(int)w);/* output to aux */
}
}
}
```

EXIT should be #defined to be the scancode of the key you want to exit the
terminal with (UNDO for instance).
I am using Gemdos for console I/O so it can be redirected.
CU
Wolfram

well, that should help. one thing, you need to #include osbind.h
<grin> BTW, thanks for the help on the term program guys!!!

>>and look for the interrupt code that writes to the Yamaha chip.

I'd like to appologise to Dave for seeming to suggest anyone use his code.
I meant only to indicate a place to see interrupt code. I was talking
about the couple of lines of hand waving the systems requires - you have
to reset interrupt pending flags or something. The last thing I would
suggest is for someone to grab Dave's code verbatim - or grab anyone's.
Nobody learns anything by just copying code.

Now, to write a Timer A interrupt:

Use the XBIOS function Xbtimer to set the vector to your handler.
Your handler should:
1. Save and restore ANY registers it uses.
2. Before you exit, clear bit 5 of $fffffa0f, the Interrupt in-service
bit for timer A.
3. Exit using RTE

That, I think, is the bare essentials. Dave would nodoubt do exactly that.
So would any other program used Timer A.

>reduced. I don't like that NCR thing very much because it's a bit CPU
>dependent.

Thanks for relating this experience, because it points me toward a possibly better solution to directly replacing the floppy controller chip with the NCR 5380. If a microcontroller (mcu) was connected to the ST DMA chip instead, then compatibility with TOS could still be retained! It would receive and translate all the WD 1772 commands to the appropriate SCSI commands for the NCR 5380.

A SCSI floppy drive would bootup and execute a program to flip a spare sound port bit which would signal the mcu that all subsequent commands are for the NCR 5380. Maybe a good mcu with huge ram buffer could be connected to multiple 5380s? Then something like OS/9 would be required???

The only problems with this approach are that I don't know WD 1772 commands and I don't have any schematics, timing data, and signal definitions for the ST. Does the Atari Developer Docs give complete info concerning the entire line of ST/TTs? If someone could provide a short review of it, it would be appreciated.

>I personally think ICD's ATARI-SCSI board is very good for using hard drives
>(including st506 things) but when it comes to using it for other purposes like

>too great to bear. Even minix-st source code doesn't help too much. My experi-
>ence is that there are so many vendor specific commands and non-standard op-
>tions for SCSI. But I suppose I must learn those things one of these days.

Since the TT has a SCSI, am I wrong to assume that Atari does have some sort of SCSI software toolkit? If not, then that should be a top priority project for them, because connecting SCSI peripherals to the Atari should be made simpler and standardized for developers. Easing the porting of SCSI peripherals would increase the value of the ST/TT line immensely.

>Sigh. I remember a chap once built a SCSI monitor on his own that displays all
>the happenings along the SCSI bus, e.g. such and such command with such and
>such arguments was issued by unit what and unit what responded etc . etc. I
>just don't feel like building one myself. I am really envious of your attach-
>ment to SCSI.

A SCSI monitor is a good idea! Maybe Atari or someone will develop one for the TT; it would be great if it was fashioned like a software debugger. Instead of forcing you to remember specific SCSI commands, it should be smart enough to let you point to a device and execute a battery of appropriate commands.

Since my STe went to Atari heaven, all I can do is think about how to make it better!

->in and (probably most important): if this place is 'official' (i.e.: is
->this place guaranteed for *all* TOS versions?)

I doubt this. The desktop just is a application. He does not export anything.

->if this is not known or not guaranteed,does anybody know how to replace
->the standard 'more'? is it just a vector in RAM or is it put in ROM?

You can replace the standard default action box by making your program
take all files in your desktop.inf file. Let *.* go to your program.

>Never has been.

When will Atari ever publish a nice clear book detailing the ST hardware
and the TOS operating system? I have the dev kit and it still leaves much
to be desired than a big wad of photocopies. Look at what C=/Am*ga provide
by way of clear references.

I recently suggested to Atari UK that they produce a programmers pack
that would include just such a book and two programming lanuages of the
purchasers choice. Comp Sci students would lap that up.

Actually I think Atari US did say once that they were working on such a book
but what became of it?

If you have already got the address of the object tree, the
address of any object n in the tree can be calculated as

tree address + n*sizeof(OBJECT)

sizeof(OBJECT) equals to 24.

From: bcc@Eyring.COM
Message-ID: <1991May6.142151.22681@Eyring.COM>
Source record: 48279

Can someone help me with a problem? My SM124 monochrome monitor experiences occasional periods of black out -- I'll be running something and everything goes dark! It lasts for a few minutes, then comes back on its own. The little green power indicator stays on, so presumably the power supply itself is ok. No, it doesn't seem related to a heat failure, since it can fail soon after turning it on. Cycling the power doesn't have any obvious effect, and I have tried it in two different systems with the same result. I haven't opened this monitor, although I have adjusted others -- non-conducting screwdriver in hand, other hand behind my back! Where's the loose connection?

>
Even if there is no drive 0 in the working chain of drives attached to
the ASCI port? ie, my ICD drives, with ASCI to SCSI adapter and drives
with SCSI id's 2 and 4? (I havn't the foggiest what ASCI id they (it?)
would have, from previous disclosures, I understand I can have an ASCI
id 0-7 for 8 different host adapters, and 0-7 SCSI id's on each?)
naw... I thought the host adapter was "transparent" and the SCSI id's on
the ASCI attached drives became the ASCI id.

Conjecture: My two drives (SCSI id's 2,4 on an ICD host) would show up
as ASCI id's 2,4 and work just fine (With ICD's software) attached to a
TT.

You should use rsrc_gaddr() only to get the address of the root object of a
tree, ie.
rsrc_gaddr (R_TREE, TREE0, &tree0Pointer);
rsrc_gaddr (R_TREE, TREE1, &tree1Pointer);

To get the addresses of objects inside a tree use pointer arithmetic:
objectPointer = tree1Pointer + OBJECT1

Now objectPointer references the object with index OBJECT1 inside the
object tree with index TREE1.

|> Does anyone know of a product that will let me connect an IBM keyboard to
|> my 520 ST??
|>
|> JEff

I put my 520ST in an IBM AT case. The motherboard, two floppies, a SCSI board, two keyboards, and a hard drive all run off the same power supply. Figuring out what to do with the keyboard was the biggest mess in this deal. The main problem is that, no matter what, you have to leave the original ST keyboard connected. It has chips on it that the motherboard needs. BUT, there is probably not enough space in the case to leave the original keyboard inside. As far as I know, these are your choices:

1) Connect a long cable to the original ST keyboard. This is simple to do, but you have to figure out how to make some kind of case for the keyboard (maybe out of wood). Also, you are stuck with the same lousy keyboard.

2) Get an IBM keyboard adapter. This way you get a better keyboard, but you still have to deal with the original ST keyboard. This can also be expensive. The Z-Keys adaptor was about $100 the last time I checked. I think there are others now, but I don't know how much they cost. On top of this, you have to buy an IBM keyboard.

3) There are instructions on the network in a file called 'deckey' (or something like that) for connecting a DEC LK201 keyboard to the ST midi or serial ports. A small software driver is included. The midi port connection requires a small hardware mod to change the baud rate of the midi port, but the serial connection requires no modifications. Unfortunately, using the keyboard on the serial port will exclude the use of a modem, and this is generally unacceptable. I am not particularly fond of the LK201, but I think that any DEC compatible keyboard will work, so maybe you can find one you like. They tend to be more expensive than IBM keyboards, I got a used one for $100.

I did both 1 and 3. The DEC keyboard is hooked to my midi port, and the two keyboards function in parallel. The modification is easy to make for someone with electronics experience, and I had no

trouble. It will take you a bit of time and some patience though. I added a switch so that I can change back to the original midi baud rate if required. The software driver is small (~1K) and very stable. I have never had any conflicts with the software that I use (but screen savers which look for keyboard input may not see this keyboard, and thus may kick in when you are typing).

Moving the ST to the IBM case was a bit of a chore, but I am happy with the result. Most of the effort goes into making the cables needed to extend all the ST ports to the back of the IBM case. Parts can be hard to find, but Best Electronics will generally have anything that you can't find locally. I strongly recommend doing the move/modifications one step at a time, making sure that the ST works at each step. Good Luck!

I had a similar problem with my SM124. I tried for a couple of years
to track it down, without success. Then I read in STWorld that it may
be a problem with the flyback transformer. So, I ordered a new flyback
(no small task) and replaced it. Unfortunately, that was not the problem.
Don't try this unless you know what you are doing.

Soon afterwards, I needed to extend the length of my monitor cable so
that I could set my computer on the floor. I got a cable from Best
Electronics and soldered it to the monitor board. This eliminated the
blacking problem. It was either the cable, or something in the connector.
Unfortunately, after adding the new cable, the quality of the screen
image was degraded (looks like interference). My best guess on the
cause of this is that the monitor cable I got is not sufficently
shielded. I have been unable to restore the original quality of the
image, but my screen no longer goes blank.

My understanding is that the ST will read ID numbers from the lowest one to the highest, and it doesn't matter if some are skipped. The TT reads from 0 up in SEQUENTIAL order. If you skip a number the others are invisible. If your TT doesn't have an internal HD then the ID 1 drive would act as you described and changing it to 0 would be the fix. Does this make sense or am I all wet? (I don't have a TT so I don't know if the manual says this. I picked it up somewhere, on GEnie maybe.)

But this would mean that any Mac software purchased would have to be
modemed or null-modemed over, which was my original point. Depending
upon your setup, and what hardware was available to you this may not
matter. By the way, do you know how much this DOS Mounter costs? I
am lucky enough to have a bunch of Macs lying around, so I was thinking
of getting a Spectre 128 myself (see, I am an exception!!).

2249. Using ST hard disks on TT's

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-06 19:04:33 UTC
From: apratt@atari.UUCP
Message-ID: <2928@atari.UUCP>
Source record: 48149
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

A couple of people have written to me complaining that their TT's only see the first four partitions of the hard disks they were using on their ST systems.

The answer to this problem is always the same: the driver is different.

Supra (and ICD?) use tricks that we don't use to get more than four partitions on a drive. We use a different trick. When you attach a drive with more than four partitions to a TT, you are using the hard-disk driver from Atari which is on the TT's internal hard disk, not the driver that understands Supra's trick.

Since these drivers probably don't work on TT's and certainly don't know about the TT's SCSI port, you are stuck. You should copy all the data off of the Supra drive, and use the HD tools that come with the TT to reformat and repartition it. These tools will let you create more than four partitions, but they'll do it the Atari way, not the Supra way.

It is possible that HDX will not be able to format your drive, because it can't tell how big it is. HDX can always tell how big SCSI drives are (that is, drives on the SCSI bus), but it can't always tell about ACSI drives. It might ask you what type of drive it is, with a menu of drive types to choose from. In either of those cases, I can't help you -- I don't know which type to choose for the various Supra drives.

Good luck.

Hello James,
You asked about the best memory upgrade for your ST. Well
there are several on the market, any of which could run you between $250 to
$400 (US). I have installed many of these, and the BEST memory upgrade
board that I would recommend is the..... Atari 1040STe.
Now you may not really want to buy a whole new computer; but in reality
it works out costing about the same as upgrading. If you find a good price on
a 1040STe, you can sell your old computer instead of upgrading it. The net
cost is about the same. Just my own rambling, bye.....

I conclude that the Supra controller responds on the ACSI bus using the unit number of the SCSI drive connected to it; see below.

> A TT system is purchased.
> The DMA cable connecting the Supra to the working ST setup is
> disconnected, and attached to the ASCI DMA port on the TT.
> The computer is booted.
> The Supra is invisible to the TT desktop, for no apparent reason.
> Nothing is stated in the manual. No error messages from the
> HDX software.

I stand corrected. I should have said, "A working system WITH ATARI DRIVERS will work when plugged into a TT." What is happening here is that on the ST, you are booting with Supra's driver off the Supra hard disk, and on the TT you are booting with Atari's driver on the TT's internal hard disk.

Supra's driver will find ACSI units which are not connected in consecutive order starting with zero, and Atari's driver won't.

The same thing would happen if you connected an ACSI drive, as ACSI unit zero, HINSTALLED with Atari's driver, to the ST: you would get Atari's driver, not Supra's. (Of course, since you now have consecutive ACSI unit numbers starting from zero, your Supra would be found; if the Supra were unit 2, it would not be.)

There is another problem which has been called to my attention, and which is covered by the same "Atari drivers" caveat: Supra uses one trick to get more than four partitions per drive, and Atari uses another. If you have a drive partitioned with Supra's trick, and you connected it to a TT (or any machine running an Atari driver) the partitions after the fourth one will not be accessible. Again, it's a question of using non-Atari drivers.

What is said here is to abandon ATARI ST and goto PC. I have been with
Motorola 680x[x] and Western Digital 1791 series for too long to go to
the other side of the trench. I admit there is nothing rational in this.
NEC's 765 (it's now called muPD72067) cannot read a sector when its size
is not known beforehand. I also admit 1791 series users tend to set
'protection' on their disks too easily. I heard that WD has gone over
to NEC's side. Bad news. But Fujitsu, the NEC's arch-enemy and the largest
computer company in Japan is still on 1791's side. I wonder why ATARI simply
don't ask FUJITSU to manufacture a WD1772 clone? ATARI won't sell enough to
pay the cost of building another chip plant. I am sure FUJITSU can sell the
WD1772 clone with a high speed mode cheaper than any other company. (
I have nothing to do with FUJITSU.)

Speaking of upgrades, the prices for MegaSTes have really surprised me.
Several places are selling the 4meg model for $1400! One of those places
was selling the 2meg model for $1300.

Of course, the 1040STe can be had for around $400.

2257. How does one write a GDOS driver?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-07 02:04:31 UTC
From: jeff@hpuplca.nsr.hp.com
Message-ID: <12400001@hpuplca.nsr.hp.com>
Source record: 48148

I'm trying to find information on how to write a GDOS device
driver from scratch. I've tried to find this in the Devel Kit
but either I missing something obvious or it's not described.
I've gotten my hands on an obscure, off-brand bed plotter that
I'd like to hack.

Jeff

>+---+

The only problem here is that 90% of Macs out there don't have the new
Super Drives. So, at this point in time, and probably for the next year
or so, a GCR would be a very viable option.

That is, if you can get it, or the ROMS.

I can help you out, if you need ROMS I am selling them for $500.

2259. A correct midi interrupt routine.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-07 07:28:22 UTC
From: geert@ahds.UUCP
Message-ID: <1985@ahds.UUCP>
Source record: 48151
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi midi gurus,

A few weeks ago someone asks for a correct midi interrupt
routine that does get rid of the mouse interfering with midi.
I wonder if someone has written such a routine.

Here's my probem:

When changing the midi vector of the standard tos calls
to your one (I don't ment midiws or Cconin) in
the particular structure (don't know the name of it because I am
writing this all of my head), does seem to work fine.

However, when bulking some midi data to the ST I (and not
only I) found out that some data will be lost. I think
that this comes because the mouse and keyboard vectors
are on the same intterupt level (to much unfortunately)

Has anyone found out how to pass this problem?

Geert

Wrong. The limititation is not in the BIOS, but in AHDI. The BIOS boots
from the first drive with an executable root sector (the TT takes the
SCSI drives first). But AHDI only looks for devices starting at #0 in
sequential order.

>up in SEQUENTIAL order. If you skip a number the others are invisible. If

2261. 3 1/2 Questions in 1 (MIDI, GDOS & GEM)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-07 10:51:03 UTC
From: goldthor@parc.xerox.com
Message-ID: <1991May7.105103.27796@parc.xerox.com>
Source record: 48288

Here are 3 (and a bit) questions for all you ST experts,

I'm writing a program to read MIDI data, I heard that the MIDI buffer is a bit small for MIDI data comming in at a fast rate (like a sequencer dump).
a) Is this true and,
b) would I get around the problem by doing something like this:
(Turn off interupts - how?)
get Iorec & replace with bigger buff
(turn interupts back on).

In sections of GEM programs I've seen, people usually check for GDOS and set up the virtual workstation stuff up slighty different if it exists. Is this necessary and why?

Are there any 'good' source GEM programs available on the net (terminator etc), as this would help me work out why my own code doesn't work at the moment (learning GEM without a book 'aint much fun).

Thanks,
-Steve Goldthorpe

Basically, you have to rewrite a whole new vdi. If you are familiar with assembler, you should take a look at the trap dispatcher at the beginning of META.SYS

Perhaps is should be mentioned that the AHDI 3 partition scheme is well documented and that it's a problem of the other hard disk manufactures if they are not compatible. There *ARE* third-party drivers that are AHDI-3 compatible AND know about the TT's SCSI port (in fact, I am one of the authors of one of them).

No, no, no! The point is that you can use DOS disk to transfer programs
and data between Spectre 128 and genuine Macs at normal disk access speeds.

> By the way, do you know how much this DOS Mounter costs?

Well I dunno for sure but word is about 60 UK pounds. I have played with a
demo version and it sure does work.

2269. How do you play Sound Samples? The answer :)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-07 19:06:43 UTC
From: friedric@unipas.fmi.uni-passau.de
Message-ID: <1991May7.190643.28309@forwiss.uni-passau.de>
Source record: 48146

```
; Hi,
; as i got many, many requests about the source-code to play digitized
; music, i decided to post it instead of mailing to everyone.
; don't be confused by the letter like style, cos i just post the
; letter i've written to the first ones.

; I DIDN'T WRITE THE SOURCE, BUT TOOK IT FROM A ST-MAGAZINE ARTICLE AND
; CHANGED IT TO FIT MY NEEDS !!! (just wanted to make this clear)

; here's the promised source-code. It is NO executable program, but to
; be compiled as an object file and linked to a C-program.
; How to use it from a C-program:

; if you want to play a sample:

; set smp_anf_ to the begining of the sound-data.
; set smp_len_ to the length of the sound-data.
; set smp_frq_ to the playing frequenzy (0 to 30.000 in Hz)
; set smp_out_ to the scan-code of the character you want to abort playing
; before the end has been reached
; set smp_way_ to 1 if you want to play forward, any other value, if want
; to play the sample reverse (really funny flag)
; set smp_mod_ to 2 for playing samples
; start with start1();

; you don't have to set 'em all, just look at the default values at the end
; of the listing.

; if you want to listen to a digitizer:

; set smp_mod_ to 0 for listening
; set smp_frq_ see above
; set smp_out_ escape character (SCAN-CODE!!!). IMPORTANT: no exit from this
; mode with an wrong scan-code !!!! only way then is reset-button
; then start1();

; if you want to record samples

; set smp_mod_ to 1
; set smp_frq_ to the frequenzy you want to sample with (0 to 20.000 in Hz)
; set smp_anf_ begining of sample-buffer
; set smp_end_ end of sample-buffer
; set smp_out_ see above. program terminates as well if reaching smp_end_
; then start1();
; in return smp_len_ is set by the program to the really sampled length

; If using a digitizer, it should be at the printer-port!
```

```
; I hope all this above is true, as wrote it more then 1 year ago, but
; you should be able to correct it by looking at the code.
; I'm not shure about copyrights, as I took a computer-magazine-article
; about a self-made sampler, and adapted their source to fit my needs.
; If they don't have the copyrights, then the rights are by me. You may
; copy it, adapt it, delete it, throw it a you're brothers head, or do what
; ever you want with it, but don't blame me for the results.
; It would be nice, if using it in a program, to insert the names Martin
; Backschat (the original author) or/and Carsten Friedrich (me :) .

; this program is written for the Devpack assembler, so you might have
; to change some lines for other assemblers. (e.g. dc.l to .dc.l)
; the program can play 8-bit samples (should be standart), but only uses
; 6-Bit, because i only have a 6-Bit sound-data-table :(. If you get hold
; of an 8-Bit table, i made a mark in the source, what you would have to
; change. (and please mail it to me .... :) )
; although working with interupts, this program always (no matter what
; smp_frq_ ) uses 100 % CPU-time. This was made to improve speed and with
; that to improve sound-quality. I made a mark in the source, with some
; hints how to change that. but smp_frq_ should not exceed 20.000 Hz when
; doing this and if you want the computer to have the time, really to work
; while playing 10.000 Hz is a kind of limit. (Remember real sound-frequenzy
; is 0.5 * sample-frequenzy !, this means setting smp_frq to 10.000 Hz means
; a real sound of 5.000 Hz )
; The program uses Timer D for interupt. If you want to uses RS232, you
; should change this to Timer A. I used Timer D, as I needed Timer A for
; more important things.

; I hope that helps you. Lables might be a bit confusing for you, as i named
; them in german.

; if using Devpack, you should be able to assemble it just as it is.
; sorry, just noticed, that it is executable, just remove the line XDEF.
; you should just add Pterm0 (gemdos(0)) if you don't like it to terminate
; with two bombs at the end, then assemble it as an executable program (*.tos)
; and you can listen to a sampler, if one is connected to the printer-port.
; to stop press space :)

; if you still have questions, or it just doesn't work, mail me and I'll try
; to help you. If you send me some money for stamps, I can send you the
; source listing of Martin Bachschat (it's a complete assemler program to deal
; with samplers at the printer port ca. 900 lines). If you send me a disc, I
; can copy the source-code and executable-code of a C-program I wrote for
; sampling and playing samples with the MarkWilliams C-compiler. It uses
; this assembler program for handling the sampler and sound out-put. I don't
; e-mail it, as it includes a .rsc file. But PLEASE don't forget to add some
; money for stamps and a disc, if you want my program.

; greetings,
; Carsten !

2270. Re: Force Desktop Res Change?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-07 19:17:32 UTC
From: bjoern@drdhh.hanse.de
Message-ID: <3094.05.91@drdhh.hanse.de>
Source record: 48191

From article <1991Apr28.014020.3838@lonex.radc.af.mil>, by longj@lonex.radc.af.mil (Jeffrey K. Long):
> Also, is there any way to force a resolution change WITHOUT a resulting
> reboot of the system. I mean, from desktop (med) to desktop (low) and vice-versa?

No, there isn't.
It's because the VDI/AES have to be initialized to the new video mode.

On ROM Systems you can call Puntaes() to do a warmboot, there was also
something about using shel_write to reinit, it used some -1 params,
but I can't find it yet and don't know it it's documented or what.

Greetings, Bjoern

2271. Re: 'GDOS printer drivers'

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-07 19:20:50 UTC
From: bjoern@drdhh.hanse.de
Message-ID: <3095.05.91@drdhh.hanse.de>
Source record: 48198

> Whilst on the subject of printer drivers in general, could someone post
> details of the 'printer.sys' file most commonly found referred to in the 'assign.sys'
with driver ID 21 ? I have a printer which emulates an Epson, but most

printer.sys is a program. VDI-Drivers are programs that are loaded upon
open_workstation and called as a function dispatcher to draw graphic
primitives. They are neither configuration-files nor just hardcopy drivers.

>(Mickey Boyd) writes:
>>In article <2896@odin.cs.hw.ac.uk>, neil@cs.hw.ac.uk (Neil Forsyth) writes:
>>>But there is a program called DOS Mounter that can be run on both Spectre 128
>>>with version 3 software and a real Mac (with a high density drive) that will
>>>allow DOS disks to be used instead of GCR ones.
>>>No need to upgrade to GCR if you don't want to.
>>
>>But this would mean that any Mac software purchased would have to be
>>modemed or null-modemed over, which was my original point.
>
>No, no, no! The point is that you can use DOS disk to transfer programs
>and data between Spectre 128 and genuine Macs at normal disk access speeds.
^^^^^^^^^^^^^^^^

<sigh>. Ok, let's go to the store. Let's buy a piece of Mac software.
We go home. Hmmm, do I have a Mac? No, but I have a Spectre 128, and that
is damn close. Hmmm, ok, let's stick this disk in. Hmmm, what is that
grungy noise . . . .

Alternate scenario: Ok, buy the software, drive home. Hmmm, disk makes a
funny noise in my (Spectre 128 equipped) ST. No problem, I'll just go over
to my Mac and put it on a DOS floppy, then walk over to my ST and smuggly
load in my new Mac program. What honey? Why did I buy this Spectre when I
already have a Mac? Well, you see, the screen is really big . . . .

NOW do you see my point? The one that might be important (either way) in
the decision to purchase a Spectre 128 or Spectre GCR! The GCR is more
convenient at worst, and if you do not have access to another Mac, it may
be a necessity. For example, if you have a Mac at work and an ST at home,
a Spectre 128 would probably be fine. Actually, if you happen to have a
Syquest SQ-555 hooked to your ST, and have access to a Mac similarly
equiped, you have it made. You can move stuff around at 44mb a pop. Much
better.

As a side note, does anyone know how to purchase the made-in-hong-kong
legitimate Mac ROMS? The ones that sell for $2 over there (or something)?
I saw the original post, but no followup (heehee, all this might be for
naught . .).

2274. PD-MS-program??

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-08 10:06:24 UTC
From: HUTTER@rzmain.rz.uni-ulm.de
Message-ID: <1991May8.121029.4680@rusmv1.rus.uni-stuttgart.de>
Source record: 48161

Hi!

Being new to this kind of communication I don't exactly know, if this message is posted to the correct newsgroup, but I hope so.

I'm looking for a (PD-)program for a ST-computer that will help in assigning mass spectra. I have heard of a program that does this but don't know where it can be found. If someone has got such a program or knows where I could get it, I'd appreciate it very much if You could let me know.

Thanks

Wolfgang

2275. Timer A, Spurious Interrupts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-08 11:01:16 UTC
From: csbrod@immd4.informatik.uni-erlangen.de
Message-ID: <1991May8.110116.3191@informatik.uni-erlangen.de>
Source record: 48162

Hi,

this is my first experiment with the MFP Timer A. I have fiddled
around with the corresponding XBIOS functions Xbtimer(), Jdisint()
and Jenabint(), and the interrupt routine proper even is called
periodically - everything fine so far. The problem is that I get
a Spurious Interrupt exception from time to time - more often if
the period between interrupts is decreased by adjusting the Timer
A data and control register.

The code I'm using looks like this:

```
Xbtimer(TIMERA, 0, 0, -1L); /* stop Timer A */
Xbtimer(TIMERA, 1, 9, myroutine); /* start Timer A */
.
.

/* do some floppy I/O */
.
.
Xbtimer(TIMERA, 0, 0, -1L); /* stop Timer A */
Jdisint(13); /* disable Timer A interrupts */
```

The interrupt routine:

```
myroutine:
addq.l #1,counter
bclr #5,$fffffa0f
rte
counter:
dc.l 0
```

I'm not dealing with any other interrupts while the routine above is running.
I'm working on a TT with TOS 3.01. If I understand the 'Spurious Interrupt'
exception right, it is triggered by some interrupt device (probably the
MFP) not responding to a CPU interrupt acknowledge cycle. I can't figure
out, however, how I did that 8-)

If somebody can help me out: Please make a simple door very happy 8-)

2276. STe extended video hardware registers

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-08 11:13:20 UTC
From: mro@dcs.exeter.ac.uk
Message-ID: <3274@izar.dcs.exeter.ac.uk>
Source record: 48165

In Mathew Lodge's articles about the new hardware in the STe, he detailed address $FF820E as

"Line offset (LINEWID) - the number of extra words added to the address counter at the end of each line ..."

I have had absolutely no success in using this register.

I have tried putting in all the different values I can think of, but the output doesn't change at all. I could understand the display being incorrect, or skewed if I put in a wrong value, but when absolutley no change occurs, I assume I am using it incorrectly.

I am accessing it using 68000, basically by going into Supervisor mode and storing a value at location $FF820E.

So, is $FF820E the wrong location, or have I just totally misunderstood what this register is supposed to achieve?

Thanks for any help

Marcus

2277. Latest Picture Formats List

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-08 14:18:29 UTC

Introductory Information
----
word = 2 bytes
long = 4 bytes
palette = Hardware color palette, stored as 16 words. First word is
color register zero (background), last word is color register
15. Each word has the form:

Bit: (MSB) 15 14 13 12 11 10 09 08 07 06 05 04 03 02 01 00 (LSB)
-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --
0 0 0 0 0 R2 R1 R0 0 G2 G1 G0 0 B2 B1 B0

R2 = MSB of red intensity
R0 = LSB of red intensity

G2 = MSB of green intensity
G0 = LSB of green intensity

B2 = MSB of blue intensity
B0 = LSB of blue intensity

Intensity ranges from 0 (color not present) to 7 (highest
intensity).

Example: { red = 7, green = 3, blue = 5 } -> 0735 (hex)

Caveat: It is wise to mask off the upper four bits of each
palette entry, since a few programs store special

information there (most notably Art Studio).

The Formats

<NEOchrome> *.NEO

1 word flag byte [always 0]
1 word resolution [0 = low res, 1 = medium res, 2 = high res]
16 words palette
12 bytes filename [usually " . "]
1 word color animation limits. High bit (bit 15) set if color
animation data is valid. Low byte contains color animation
limits (4 most significant bits are left/lower limit,
4 least significant bits are right/upper limit).
1 word color animation speed and direction. High bit (bit 15) set
if animation is on. Low order byte is # vblanks per step.
If negative, scroll is left (decreasing). Number of vblanks
between cycles is |x| - 1
1 word # of color steps (as defined in previous word) to display
picture before going to the next. (For use in slide shows)
1 word image X offset [unused, always 0]
1 word image Y offset [unused, always 0]
1 word image width [unused, always 320]
1 word image height [unused, always 200]
33 words reserved for future expansion
16000 words picture data (screen memory)

32128 bytes total

<NEOchrome Animation> *.ANI

NOTE: To get this feature on versions 0.9 and later select the Grabber
icon and click both mouse buttons in the eye of the second R in the
word GRABBER.
Interestingly enough, some versions of NEO only require you
to press the right button, not both. Hmmm...

1 long magic number BABEEBEA (hex) (seems to be ignored)
1 word width of image in bytes (always divisible by 8)
1 word height of image in scan lines
1 word size of image in bytes + 10 (!)
1 word x coordinate of image (must be divisible by 16) - 1
1 word y coordinate of image - 1
1 word number of frames
1 word animation speed (# vblanks to delay between frames)
1 long reserved; should be zero
----
22 bytes total for header

? words image data (words of screen memory) for each frame, in
order

<DEGAS> *.PI1 (low resolution)
*.PI2 (medium resolution)
*.PI3 (high resolution)

1 word resolution (0 = low res, 1 = medium res, 2 = high res)
Other bits may be used in the future; use a simple bit
test rather than checking for specific word values.
16 words palette
16000 words picture data (screen memory)

32034 bytes total

<DEGAS Elite> *.PI1 (low resolution)
*.PI2 (medium resolution)
*.PI3 (high resolution)

1 word resolution (0 = low res, 1 = medium res, 2 = high res)
Other bits may be used in the future; use a simple bit
test rather than checking for specific word values.
16 words palette
16000 words picture data (screen memory)
4 words left color animtion limit table (starting color numbers)
4 words right color animation limit table (ending color numbers)
4 words animation channel direction flag (0 = left, 1 = off, 2 = right)
4 words 128 - animation channel delay in 1/60's of a second. [0 - 128]
(I.e., subtract word from 128 to get 1/60th's of a second.)

32066 bytes total

<DEGAS Elite (Compressed)> *.PC1 (low resolution)
*.PC2 (medium resolution)
*.PC3 (high resolution)

1 word resolution (same as Degas, but high order bit is set;
i.e., hex 8000 = low res, hex 8001 = medium res,
hex 8002 = high res). Other bits may be used in the
future; use a simple bit test rather than checking
for specific word values.
16 words palette
< 32000 bytes control/data bytes
4 words left color animation limit table (starting color numbers)
4 words right color animation limit table (ending color numbers)
4 words animation channel direction flag [0 = left, 1 = off, 2 = right]
4 words 128 - animation channel delay in 1/60's of a second. [0 - 128]
(I.e., subtract word from 128 to get 1/60th's of a second.)

< 32066 bytes total

Compression Scheme:

PackBits compression is used (see below). Each scan line is compressed
separately; i.e., all data for a given scan line appears before any data
for the next scan line. The scan lines are specified from top to bottom

(i.e., 0 is first). For each scan line, all the data for a given bit plane appears before any data for the next higher order bit plane. Note this is identical to the IFF 'BODY' image data.
To clarify: The first data in the file will be the data for the lowest order bit plane of scan line zero, followed by the data for the next higher order bit plane of scan line zero, etc., until all bit planes have been specified for scan line zero. The next data in the file will be the data for the lowest order bit plane of scan line one, followed by the data for the next higher order bit plane of scan line one, etc., until all bit planes have been specified for all scan lines.

Caveats:

DEGAS Elite's picture loading routine places some restrictions on compressed DEGAS files:

o Elite uses a 40-byte buffer to store data being decompressed.

o Whenever a control command is encountered, bytes are stuffed in this buffer.

o The buffer is only emptied when there are EXACTLY 40 characters in it.

The important conclusion here is that

No control command may cause the buffer to have more than 40 bytes in it. In other words, all control commands must end on or before the 40-byte boundary.

Any picture violating the last condition will cause Elite to get a bus error when the picture is loaded.

<Tiny> *.TNY (any resolution)
*.TN1 (low resolution)
*.TN2 (medium resolution)
*.TN3 (high resolution)

Several people have reported sightings of mutated Tiny pictures that do not follow the standard format, so let's be careful out there. What is described here is the format that David Mumper's original TNYSTUFF.PRG produces.

1 byte resolution (same as NEO, but +3 indicates rotation information also follows)

If resolution > 2 {
1 byte left and right color animation limits. High 4 bits hold left (start) limit; low 4 bits hold right (end) limit
1 byte direction and speed of color animation (negative value indicates left, positive indicates right, absolute value is delay in 1/60's of a second.
1 word color rotation duration (number of iterations)

}

16 words palette
1 word number of control bytes
1 word number of data words
3-10667 bytes control bytes
1-16000 words data words

42-32044 bytes total

Control byte meanings:

For a given control byte, x:

x < 0 Absolute value specifies the number of unique words to
take from the data section (from 1 to 127)
x = 0 1 word is taken from the control section which specifies
the number of times to repeat the next data word (from
128 to 32767)
x = 1 1 word is taken from the control section which specifies
the number of unique words to be taken from the data
section (from 128 - 32767)
x > 1 Specifies the number of times to repeat the next word
taken from the data section (from 2 to 127)

Format of expanded data:

The expanded data is not simply screen memory bitmap data; instead, the
data is divided into four sets of vertical columns. (This results in
better compression.) A column consists of one specific word taken
from each scan line, going from top to bottom. For example, column 1
consists of word 1 on scanline 1 followed by word 1 on scanline 2, etc.,
followed by word 1 on scanline 200.
The columns appear in the following order:

1st set contains columns 1, 5, 9, 13, ..., 69, 73, 77 in order
2nd set contains columns 2, 6, 10, 14, ..., 70, 74, 78 in order
3rd set contains columns 3, 7, 11, 15, ..., 71, 75, 79 in order
4th set contains columns 4, 8, 12, 16, ..., 72, 76, 80 in order

Note that Tiny partitions the screen this way regardless of resolution; i.e.,
these aren't bitplanes. For example, medium resoltion only has two bitplanes,
but Tiny still divides medium resolution pictures into four parts.

<Spectrum 512> *.SPU

80 words first scan line of picture (unused) -- should be zeroes
15920 words picture data (screen memory) for scan lines 1 through 199
9552 words 3 palettes for each scan line (the top scan line is
not included because Spectrum 512 can't display it)

51104 bytes total

Note that the Spectrum 512 mode's three palette changes per scan
line allow more colors on the screen than normally possible, but a
tremendous amount of CPU time is required to maintain the image.

The Spectrum format specifies a palette of 48 colors for each scan line.
To decode a Spectrum picture, one must be know which of these 48 colors
are in effect for a given horizontal pixel position.

Given an x-coordinate (from 0 to 319) and a color index (from 0 to 15),
the following C function will return the proper index into the Spectrum
palette (from 0 to 47):

```
/*
* Given an x-coordinate and a color index, returns the corresponding
* Spectrum palette index.
*
* by Steve Belczyk; placed in the public domain December, 1990.
*/
int
FindIndex(x, c)
int x, c;
{
int x1;

x1 = 10 * c;

if (1 & c) /* If c is odd */
x1 = x1 - 5;
else /* If c is even */
x1 = x1 + 1;

if (x >= x1 && x < x1 + 160)
c = c + 16;
else if (x >= x1 + 160)
c = c + 32;

return c;
}
```

<Spectrum 512 (Compressed)> *.SPC

```
1 word flag word [$5350 or "SP"]
1 word reserved for future use [always 0]
1 long length of data bit map
1 long length of color bit map
<= 32092 bytes compressed data bit map
<= 17910 bytes compressed color bit map
--------------
<= 50014 bytes total
```

Data compression:

Compression is via a modified run length encoding (RLE) scheme,
similar to DEGAS compressed and Tiny. The data map is stored as a
sequence of records. Each record consists of a header byte followed by

one or more data bytes. The meaning of the header byte is as follows:

For a given header byte, x:

0 <= x <= 127 Use the next x + 1 bytes literally (no repetition)
-128 <= x <= -1 Use the next byte -x + 2 times

The data appears in the following order:

1. Picture data, bit plane 0, scan lines 1 - 199
2. Picture data, bit plane 1, scan lines 1 - 199
3. Picture data, bit plane 2, scan lines 1 - 199
4. Picture data, bit plane 3, scan lines 1 - 199

Decompression of data ends when 31840 data bytes have been used.

Color map compression:

Each 16-word palette is compressed separately. There are three
palettes for each scan line (597 total). The color map is stored as a
sequence of records. Each record starts with a 1-word bit vector which
specifies which of the 16 palette entries are included in the data
following the bit vector (1 = included, 0 = not included). If a palette
entry is not included, it is assumed to be zero (black). The least
significant bit of the bit vector refers to palette entry zero, while the
most significant bit refers to palette entry 15. Bit 15 must be zero,
since Spectrum 512 does not use palette entry 15. Bit 0 should also be
zero, since Spectrum 512 always makes the background color black.
The words specifying the values for the palette entries indicated in
the bit vector follow the bit vector itself, in order (0 - 15).

<Art Director> *.ART (low resolution only)

16000 words picture data (screen memory)
16 words palette
15 * 16 words 15 more palettes for animation

32512 bytes total

<C.O.L.R. Object Editor Mural> *.MUR (low resolution only)

16000 words picture data (screen memory)
(palettes are stored in separate files)

32000 bytes total

<Doodle> *.DOO (high resolution only)

16000 words picture data (screen memory)

32000 bytes total

<Animatic Film> *.FLM (low resolution only)

```
1 word number of frames
16 words palette
1 word speed (0 - 99; value is 99 - # vblanks to delay between frames)
1 word direction (0 = forwards, 1 = backwards)
1 word end action (what to do after the last frame)
0 = pause, then repeat from beginning
1 = immediately repeat from beginning
2 = reverse (change direction)
1 word width of film in pixels
1 word height of film in pixels
1 word Animatic version number (major)
1 word Animatic version number (minor)
1 long magic number 27182818 (hex)
3 longs reserved for expansion (should be all zeros)
--------
32 words total for header

? words image data (words of screen memory) for each frame, in order

<GEM Bit Image> *.IMG

1 word version number of image file [1]
1 word length of header in words [usually 8]
1 word number of color planes [1 for monochrome]
1 word pattern length in bytes [1-8, usually 2 for screen images]
1 word pixel width in microns (1/1000 mm, 25400 microns per inch)
1 word pixel height in microns
1 word line width in pixels
1 word number of lines
-------
? words header length defined in 2nd word of header

? bytes data

NOTES: If the image is a color image (planes > 1), the planes are stored
separately starting with plane 0. There is, however, no standard way of
storing the color palette. Some programs may save the palette in separate
files, some may extend the header. For this reason, you should never
assume the header is 8 words long, always get the header length from the
2nd word of the header. Also, the line width in the 7th word is the number
of pixels in a line. Since the data is encoded in byte-wide packets, the
actual unpacked line width is always a multiple of 8, and may be 1-7 pixels
longer than the length specified in the header.

For each byte x in the data section,

x = 0 Pattern/scanline run.
Read the next byte, n (unsigned).

If n > 0 then:
Read a number of bytes equal to the "pattern
length" word in the header. Repeat this
pattern n times.
```

If n = 0 then:
Scanline run. Data for the next scanline
is to be used multiple times. Read the
following record:

1 byte flag byte [$FF]
1 byte number of times to use
next scanline data

The data for the next scanline follows,
compressed normally.

x = 80 (hex) Uncompressed bit string. The next byte
determines the number of bytes to use
literally. The literal data bytes follow.

otherwise Solid run. The value of x determines
what to draw. The high bit specifies whether
the pixels are set or cleared. A 1 indicates
a byte-run using $FF, a 0 indicates a byte-run
using $00. The low 7 bits, taken as an unsigned
quantity, specify the length of the run in bytes.

<STAD> *.PAC (high resolution only)

4 bytes "pM86" (vertically packed) or "pM85" (horizontally packed)
1 byte id byte
1 byte pack byte (most frequently occuring byte in bitmap)
1 byte "special" byte
----
7 bytes total for header

? bytes data

The data is encoded as follows. For each byte x in the data section:

x = id byte Read one more byte, n. Use pack byte
n + 1 times.
x = "special" byte Read two more bytes, d, and n (in order).
Use byte d n times.
otherwise Use byte x literally.

<Imagic Film/Picture> *.IC1 (low resolution)
*.IC2 (medium resolution)
*.IC3 (high resolution)

4 bytes "IMDC"
1 word resolution (0 = low res, 1 = medium res, 2 = high res)
16 words palette
1 word date (GEMDOS format)
1 word time (GEMDOS format)
8 bytes name of base picture file (for delta compression), or zeroes
1 word length of data (?)
1 long registration number
8 bytes reserved

```
1 byte compressed? (0 = no, 1 = yes)

If compressed {
1 byte delta-compressed? (-1 = no, > -1 = yes)
1 byte ?
1 byte escape byte
}
-------
65 bytes total for header (68 bytes if compressed)

? bytes data

Compressed data may be either stand-alone or delta-compressed (relative
to the base picture named in the header). Delta compression involves
storing only how the picture differs from the base picture (i.e., only
portions of the screen that have changed are stored). This is used to
to encode animated sequences efficiently.

Compressed data, stand-alone:

For each byte x in the data section:

x = escape byte Read one more byte, n. (n is unsigned).

If n >= 2, use the next byte n times.
If n = 1, keep reading bytes until a
byte k not equal to 1 is encountered.
Then read the next byte d.
If the number of 1 bytes encountered is o,
use d (256 * o + k) times. I.e.,

if (n == 1) {
o = 0;
while (n == 1) {
o++;
n = next byte;
}

k = n;
d = next byte;

Use d (256 * o + k) times.
}
else {
d = next byte;
Use d (n) times.
}

x != escape byte Use x literally.

Compressed data, delta compressed:

For each byte x in the data section:

x = escape byte Read one more byte, n. (n is unsigned).
```

If n >= 3, use the next byte n times.
If n = 1, do the same as for n = 1 in
stand-alone compression (above).
If n = 2, then set n = next byte.
If n = 0, end of picture.
If n >= 2, take n bytes from base
picture.
If n = 1, do the same as for n = 1
in stand-alone compression (above),
but take (256 * o + k) bytes from
base picture.

x != escape byte Use x literally.

<IFF Format> *.IFF

4 bytes "FORM" (FORM chunk ID)
1 long length of file that follows
4 bytes "ILBM" (InterLeaved BitMap file ID)

4 bytes "BMHD" (BitMap HeaDer chunk ID)
1 long length of chunk [20]
20 bytes 1 word = image width in pixels
1 word = image height in lines
1 word = image x-offset [usually 0]
1 word = image y-offset [usually 0]
1 byte = # bitplanes
1 byte = mask (0=no, 1=impl., 2=transparent, 3=lasso)
1 byte = compressed [1] or uncompressed [0]
1 byte = unused [0]
1 word = transparent color (for mask=2)
1 byte = x-aspect [5=640x200, 10=320x200/640x400, 20=320x400]
1 byte = y-aspect [11]
1 word = page width (usually the same as image width)
1 word = page height (usually the same as image height)

4 bytes "CMAP" (ColorMAP chunk ID)
1 long length of chunk [3*n where n is the # colors]
3n bytes 3 bytes per RGB color. Each color value is a byte
and the actual color value is left-justified in the
byte such that the most significant bit of the value
is the MSB of the byte. (ie. a color value of 15 ($0F)
is stored as $F0) The bytes are stored in R,G,B order.

4 bytes "CRNG" (Color RaNGe chunk ID)
1 long length of chunk [8]
8 bytes 1 word = reserved [0]
1 word = animation speed (16384 = 60 steps per second)
1 word = active [1] or inactive [0]
1 byte = left/lower color animation limit
1 byte = right/upper color animation limit

```
4 bytes "CAMG" (Commodore AMiGa viewport mode chunk ID)
1 long length of chunk [4]
1 long viewport mode bits (bit 11 = HAM, bit 3 = interlaced)

4 bytes "BODY" (BODY chunk ID)
1 long length of chunk [# bytes of image data that follow]
? bytes actual image data

NOTES: Some of these chunks may not be present in every IFF file, and may
not be in this order. You should always look for the ID bytes to find a
certain chunk. All chunk IDs are followed by a long value that tells the
size of the chunk. This is the number of bytes that FOLLOW the 4 ID bytes
and size longword. The exception to this is the FORM chunk. The size
longword that follows the FORM ID is the size of the remainder of the file.
The FORM chunk must always be the first chunk in an IFF file.

The R,G,B ranges of AMIGA and ST are different (AMIGA 0...15, ST 0...7),
as is the maximum number of bitplanes (AMIGA: 5, ST: 4).

Format of body data

An expanded picture is simply a bitmap. The packing method is PackBits
(see below), and is identical to MacPaint and DEGAS Elite compressed.

The (decompressed) body data appears in the following order:

line 1 plane 0 ... line 1 plane 1 ... ... line 1 plane m
[line 1 mask (if appropriate)]
line 2 plane 0 ... line 2 plane 1 ... ... line 2 plane m
[line 2 mask (if appropriate)]
...
line x plane 0 ... line x plane 1 ... ... line x plane m
[line x mask (if appropriate)]

The FORM chunk identifies the type of data:

"ILBM" = interleaved bit map
"8SVX" = 8-bit sample voice
"SMUS" = simple music score
"FTXT" = formatted text (Amiga)

<MacPaint> *.MAC

1 long version number [0=ignore header, 2=header valid]
38 * 8 bytes 8x8 brush/fill patterns. Each byte is a pattern row,
and the bytes map the pattern rows top to bottom. The
patterns are stored in the order they appear at the bottom
of the MacPaint screen top to bottom, left to right.
204 bytes unused
-------------
512 bytes total for header

< 51200 bytes compressed bitmap data
-------------
< 51712 bytes total
```

NOTE: The version number is actually a flag to MacPaint to indicate if
the brush/fill patterns are present in the file. If the version is 0,
the default patterns are used. Therefore you can simply save a MacPaint
file by writing a blank header (512 $00 bytes), followed by the packed
image data.

Bitmap compression:

The bitmap data is for a 576 pixel by 720 pixel monochrome image.
The packing method is PackBits (see below). There are 72 bytes per
scan line. Each bit represents one pixel; 0 = white, 1 = black.

<PackBits Compression Algorithm>

The following packing algorithm originated on the Mac, was adopted by
Electronic Arts/Commodore for use in the IFF standard, and then by Tom
Hudson for use in DEGAS Elite. The algorithm is currently used in
MacPaint, IFF, and DEGAS Elite compressed file formats. Each scan line
is packed separately, and packing never extends beyond a scan line.

For a given control byte 'n':
0 <= n <= 127 : use the next n + 1 bytes literally (no repetition).
-127 <= n <= -1 : use the next byte -n + 1 times.
n = -128 : no operation, not used.

A fair bit of discussion has been on about connecting keyboards to 520 and 1040 ST models. I am surprised to see no mention of using a Mega ST keyboard. Surely one of these would need no interfacing and require only a suitable plug for connection. Does anyone know how prices compare? The old Mega has the nicest keyboard and box design of all the Atari ST/TT range (and most other desktop computers).

I have an SM124 (which has performed flawlessly since 1985) and I was considering getting an Atari colour monitor. Then I decided to get a multisync, so I could use it on other computers. I had thought that I would have to keep my SM124 for monochrome, because of the 70HZ refresh, but I recently heard that some multisyncs can do the higher rate.

Who has done this? Does it work well for both mono and colour? And what multisyncs can handle 70Hz?

2283. appl-id of running aes-process

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-09 00:04:19 UTC
From: tolk@opal.cs.tu-berlin.de
Message-ID: <3275@troll.cs.tu-berlin.de>
Source record: 48169

Is there a way to find out the appl_id of the currently running program?
It seems as if application 1 is GEM's screenmanager, 2 and above are
accessories and 0 is the id of a loaded application. Does this hold in
any circumstances?

Is it possible to get the appl_id of the application that is owner of the
topmost window? Even if the running loaded application has id 1, there could
always be an accessory that has opened the topmost window.

The background: I'm working on an accessory that sends window-messages to
the currently running application. It works fine - even with the desktop -
as long as there are no accessory-owned windows. I'm sending the messages
via appl_write to application 1 with the window-handle returned by
wind_get(0,WF_TOP,...)

I've connected a NEC Multisync II to my ST. I've tried monochrome in its
monochrome mode (forgot how), and by putting the mono signal simultaneously
to the R, G and B signals. The NEC monochrome mode is VERY grainy. Putting
the mono signal onto RG&B simultaneously has good resolution, but the screen
image is only about 1/3 of the screen height. Keep your SM124.

Source record: 48171

I have written a formatting program and a guide to install high density
drives in our ST. The document is about 34K and the binary is 5K.
I don't think they are good enough to be published in terms of explanation
style and so on, so I want people to proof read them or test themselves.
The documents deals with all the aspects of floppy drives and if any
question arises I will add all the answers to it. The formatting program
does the physical formatting in IBM standard on high/normal density
drives and also writes DOS 4.0 specific initial data on the first track.
If you are interested, please e-mail me to
ytsuji@jpnwas00.BITNET or ytsuji@cfi.waseda.ac.jp
P.S.
I've sent both of these to the atari.st moderator but it seems to take another
few weeks to get them published. I now feel uneasy.

There have been a number of people asking about connecting multisyncs
to an ST. It seems to be contagious. :^)

In that case, there is a collection of text files about connecting a
multisync monitor to an ST in the multsync.lzh file in the atari/graphics/
directory at atari.archive.umich.edu.

I have an NEC 3D connected to an STe. I'm using an IB Computers Switchbox;
they import the switchbox from Europe. I've tried the Omniswitch from
Talon Computers and it just plain sucks -- avoid it. The NEC 3D and IB
switchbox works great! No complaints.

A friend of mine has a Mistubishi Diamondscan connected to his STe. He
says that his monochrome isn't as clear.

I've heard good things about the Sony 1302 monitor.

Justin Dubois has ordered a Loop monitor to connect to his ST. He says
he should have it in a few days. We'll see what happens. :^)

Source record: 48174

I just saw this post in misc.forsale.computers. Do you think it
would work in an STe? The STe has a square, socketed 68000, right?
(I don't want to open up my machine and look. :^) Would there be a
considerable speed increase with a 68020 and 68881?!

I have this little board that converts (plugs into a 68000 scoket)
a 68000 to a 68020 with FPU (68881). The board has three PALs,
a 12 MHz 68020 and 16 MHz 68881. All parts are socketed.
The board is made by:
Computer System Associates
7562 Trade Street
San Diego, CA 92121
(619) 566-3911

I have NO documentation. This board is sold AS IS.
I have no idea if it works.

Asking $40 or best offer. Buyer pays shipping.
for another $40 I'll through in a spare set of
CPU (68020 16 mHz) & FPU (68881 16 mHz).

In article <97.28257a4c@sugaree.uu.net> bill@sugaree.uu.net (William Bishop) writes:
|Did'ya ever wonder what it would be like to use an Atari that has a
|detached keyboard...
.
.
.
|My question is: Is the a kit or something that will enable me (and
|others like me with 520's) to convert to a "box and seperate keyboard"

"Or something"

I've got a detached keyboard - A Mega keyboard, for that matter - attached to the 520 I'm using now. It's a trivially simple modification, if you're willing to do some wire fitting. What you need is a 6-wire telephone jack and a 17-pin single inline header plug (plus, of course, a Mega keyboard and a 520 - dunno about the newer ones, but the older (no internal flopsies) 520's are happy with this modification.)

4 simple steps, with appropriate cursing relative to success.

1: take apart the 520, remove the old keyboard, leap on it a few times, tear apart your warranty (leaping on the 520 keyboard provided incentive to do the modification properly, tearing apart the warranty just saves the people at Atari the effort...)

2: take the telephone jack (er, socket, or whatever - I bought a 6-pin wall plug and ripped it apart) and run the wires to the header plug as follows:
blue, yellow -> pin 1
white, black -> pin 13
green -> pin 14
red -> pin 15

(my notes - I can't look at the actual connector for obvious reasons - say that the blue wire is #1, yellow #2, white #5, black #6, green #3 and red #4 on the telephone jack or socket or whatever)

3: plug the header plug back into the 520 at the same place you took out the old keyboard. (Pin one is towards the front of the unit, in case it's not labeled on the PC board.) feed the un-keyboarded end of the Mega keyboard cable through the RF shield where the 520 cable went in, then reassemble the whole mess.

4: plug in in and play. You'll have to relocate the mouse cable out to the Mega keyboard from the ST itself, but that's the only difference I've noticed.

Total cost? 1 mega keyboard plus about $6 for the bits. And it's trivially simple, and it doesn't permanently modify _any_ of the offending bits except for the telephone jack and the the 17-pin header plug. I'm noted for my tendency to kill hardware by a glance, but I've managed to rip apart the ST, attach this mod, and put it all back together with no ill-effects so far. (But I guess I'll haveta point out that you're on your own if you do this; I'm not responsible in general, and it'd be inconsistant if I made an exception in this case.)

Have fun...

Message-ID: <1991May9.064457.19554@rodan.acs.syr.edu>
Source record: 48176

I'm trying to write a GEM application, and I'd like to use keyboard equivalents for menu item selection. How is this done? I see keyboard equivalents mentioned in the docs, but how do I add them to the resource file? And how does the application know that a keypress is a menu equivalent? Is there some AES function that will tell you if a keypress is a menu shortcut? Any help would be appreciated...

> of META.SYS

I don't quite agree. What you need is a trap dispatcher. True.
Meta.Sys is a good example for that.

Secondly, you need the code for all the functions to set and inquire
parameters. That code is basically the same for all devide drivers.
(From what I understand Atari supplies it with the GDOS Drivers Kit,
which costs about $300.) If you're not rich take a look into some device
driver. It's all in there.
(BTW: The *old* versions have a symbol table!)

What you have to write yourself is the code for the actual output.
A dot matrix printer has to buffer te output for a whole page.
It draws on a bitmap and then prints it. A plotter probalby is able to
do the drawing right when it gets the command.

Good luck,
Jan

Just a quick question about Syquest drives.
As the Mac uses a SCSI interface (25 Pin) and the ICD host board
provides a SCSI port (50 Pin) and there are such things as 25 to 50 way SCSI
connectors. Is it possible to use one of the very cheap Mac Syquest
drives with the above setup?
Or is this a dumb question ?

The current main application has the apid 0 - but this will almost
certainly fail when Atari gives us something like a MultiDesktop one day.
You could try out what happens in such a environment by testing your
program under MultiGEM.

>Is it possible to get the appl_id of the application that is owner of the

Just some illegal idea 8-) : Intercept the AES trap and look for
WF_TOP messages sent to any application. By looking in this application's
GLOBAL field you could find out its ID.

Unless I'm doing it all wrong, you call evnt_multi() and look at the
returned value to determine whether you've received a menu message,
a keystroke, or whatever. Then you either evaluate the contents of
the message buffer or look at the keystroke values, as appropriate.
(This is why GEM programs wind up with such hellishly long sequences of
nested switch-case statements.)

All the resource file does is describe objects to be drawn. The convention
for indicating that there is an ALT key alias for a menu function is that
little doohickey that looks like a reverse-video gunsight, but I don't
recall what control-keystroke produces it.

I would think it would be in Atari's best interests to provide an
upgrade path for present ST users of Supra's drives. It shouldn't
be too hard to extend AHDI so that:

1. The driver will work like Supra's driver and find ACSI units
which are not connected in consecutive order.

2. The driver will recognize Supra's extended partitions as well as
Atari's. HDX doesn't have to create them, but it would sure be nice
if AHDI and HDX understood them.

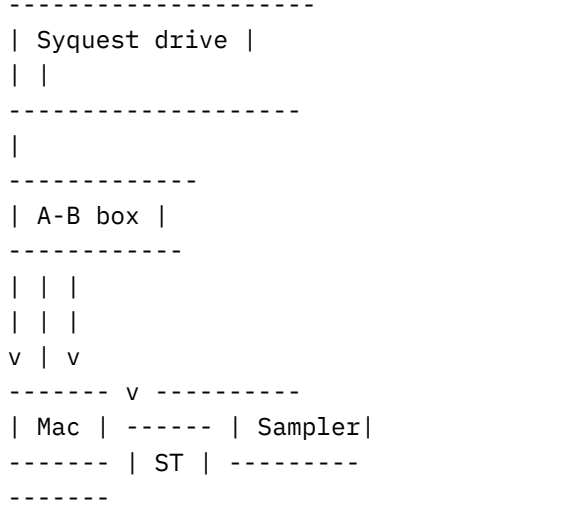
> Is it possible to use one of the very cheap Mac Syquest
>drives with the above setup?
>sean@cs.hw.ac.uk

I'm presently using a syquest drive with my ST, Mac, and Digital Sampler (sound module). It is from Third Wave, a third party Mac hardware dealer.

I got and ICD host adapter, stuck it in a box, and made a cable from the ICD so you could use a 50 pin SCSI connector. I go from there to an A-B box that lets me switch the drive between the ST and Mac and Sampler.



With this setup I can for example boot with the Mac, get into a program, then unmount the drive and boot the ST (with an ST formatted disk). Depending on the type of disk access the Mac program needs, I may or may not be able to continue processing on the Mac. But I can unmount the ST disk, and reinsert the Mac disk, and then continue processing on the Mac without rebooting.

These Syquest drives are great for poor people like me who can't afford three separate hard drives. About $70 for a removable disk and you have virtually another drive.

2297. ARGV spec repost as promised

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-09 21:18:36 UTC
From: apratt@atari.UUCP
Message-ID: <2934@atari.UUCP>
Source record: 48188
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

In a discussion about Pexec and command lines, the question of the ARGV standard came up. Here is our documentation on this convention. It dates from August 22, 1990.

GEMDOS EXTENDED ARGUMENT (ARGV) SPECIFICATION

Introduction

The Pexec() function of GEMDOS allows a program to pass to a child process a command line up to 125 characters long, with arguments separated by spaces. No provision is made in GEMDOS for the child to know its own name. This makes it difficult for C programs to correctly fill in argv[0], the standard place where a C program finds the command which invoked it. Because the command line arguments are separated by spaces, it is difficult to pass an argument with an embedded space. This document will specify a method of passing arguments which allows arbitrary argument length, embedded spaces, and support for argv[0].

Standard Argument Passing

The Pexec Cookbook specifies how to use Pexec() to launch a child process, passing a command tail (argument string) and an environment. Before getting into the extended argument scheme, let's review how arguments are normally passed to a child.

A parent process builds a command line into an argument string - a null terminated string whose first byte contains the length of the rest of the string - and its address is passed as one of the arguments to Pexec(). GEMDOS copies this argument string to the basepage which it creates for the child. Thus the parent is responsible for gathering all the child's arguments into one string. This is normally handled by a library exec() function. The child is responsible for parsing the string of space-separated arguments back into an array of strings. This parsing is normally handled by the child's startup code.

Evolution

Several methods of bypassing the limits imposed by Pexec() have been used by GEMDOS programs. Some allow a user to specify a file on the command line which contains the rest of the arguments. Others get a pointer to the arguments, or the arguments themselves, from the environment string. Most MS-DOS programs use a command file for the extra arguments. This can be inconvenient for a user, cluttering the file system with command files, and making the operation of batch files and makefiles more confusing.

Several "standards" have arisen on the ST which use the environment to pass arguments. While more convenient than command files, these standards have other problems. Some rely on sharing memory between parent and child processes. Some take advantage of undocumented features of the operating system to get argv[0]. Others give the child process no way to validate that the arguments it finds are intended for it.

Rationale

In order to pass more than the standard 125 characters worth of arguments to a child, or to let the child find its name, the parent must place the extra information in a place where the child can access it safely and legally. The most convenient place is in the child's environment string. An environment string is a series of null-terminated strings of the format "VARIABLE=value" (e.g. PATH=c:\bin,c:\etc, or ShellP=YES). The last null-terminated string in the environment is followed by a zero byte, thus two consecutive nulls indicates the end of the environment. The environment is allocated for the child by GEMDOS, it is owned by the child, and its contents can be specified by the parent.

The child must have some way of knowing that the arguments which it finds in its environment are intended for it. The child may have been invoked by a parent which does not conform to this specification. Such a parent would leave _its_ arguments in the environment, and could pass that environment on to the child. The child would mistakenly interpret its parent's arguments as its own.

Placing arguments in the environment passed to the child gets around all of the command line limits of the standard Pexec() command tail. Because there is no limit on the length of the environment, arbitrary length arguments are supported. Arguments placed in the environment are null terminated, so they may contain spaces. A parent can also place the name of the command with which it invokes the child in the child's environment, providing support for argv[0]. Validation of the extended arguments can be placed in the standard Pexec() command line, by assigning a special meaning to an invalid length byte.

The GEMDOS Extended Argument Specification

This specification uses the convention that the presence of an environment variable named ARGV (all upper case) indicates that extended arguments are being passed to the child in its environment. This means that ARGV is a "boolean" environment variable. For the purpose of this specification, its value is not significant, but its presence indicates that the strings following it are the arguments for the child. Implementations of this specification are free to give the ARGV environment variable any value. The ARGV environment variable must be the last one in the environment passed to the child, so that the child can truncate its environment at that point, and treat everything before the ARGV as environment, and everything after it as arguments.

The first argument to the child (argv[0]) is the first string in the environment after the ARGV variable. This argument is the "pathname" parameter passed by the parent to Pexec(). The remaining arguments are those that the child would normally find in the command tail in its basepage. Even if all of the arguments would normally fit in a child's command tail, the parent should set up the arguments in the environment to take advantage of the benefits of this extended argument scheme.

As many arguments as will fit in the command tail will be passed there as well as in the environment, to support non-conforming programs. As a flag that arguments are also in the environment, the length byte of the command tail will be 127 (hex 7f). Non-conforming programs should not have a problem with this length byte, because it is longer than the maximum 125 bytes allowed by Pexec().

As an aside, the Pexec Cookbook erroneously implies that a command line can be 126 or 127 characters long. In fact, GEMDOS only copies to the child's basepage up to 125 bytes, or until it encounters a null, from the argument string passed to Pexec(). It ignores the length byte, placing a null at the same place it found one or at the 126th byte if no null is found. This has several implications: the length byte is not validated by GEMDOS (necessitating validation in the child's startup code, but also making this extended argument spec possible), and the null terminator _can_ be located after the end of the real command tail (the Desktop places a CR character after the command tail and before the null). The ARGSTART.S startup code listing below demonstrates how to correctly validate and parse a GEMDOS command tail.

A child which finds an ARGV environment variable can use the command tail length byte value of 127 to validate that the arguments following the variable are valid, and not just left over from a non-conforming parent which left its own ARGV arguments in the environment.

Because the strings in the environment following an ARGV variable are not environment variables, a child should truncate its own environment at the ARGV variable by changing the 'A' to a null.

Implementation: Parental Responsibilities

To pass arguments in the environment, a parent must create an environment string for the child. This can be achieved by first allocating as much space as is used in the parent's own environment, plus enough room for the ARGV variable and the arguments to the child, and then copying the parent's environment to the newly allocated area. Next, the ARGV variable must be appended, since it must be the last variable in the child's environment string. Following the ARGV variable is the null-terminated pathname of the child as passed to Pexec(), then the null-terminated arguments to the child, followed by a final null byte indicating the end of the environment.

After setting up the arguments in the environment, the parent must place as many arguments as it can fit in the command tail it passes to Pexec(). This way, a child which does not conform to this

specification can still get arguments from the command tail in its basepage. When placing arguments in the environment, the parent must set the first (length) byte of the command tail to 127 (hex 7f), validating the arguments in the environment.

Here is an example execv() library routine in C. It uses three local utility routines, e_strlen(), e_strcpy(), and str0cpy() for getting environment size and copying strings into the environment created for the child.

```
/* EXECV.C - example execv() library routine
* ============================================================
* 890910 kbad
*/

long Malloc( long nbytes );
long Pexec( short mode, char *filename, char *tail, char *env );
long Mfree( void *address );

/* Return the total length of the characters and null terminators in
* an array of strings.
* `strings' is an array of pointers to strings, with a null pointer
* as the last element.
*/
static long
e_strlen( char *strings[] )
{
char *pstring;
long length = 0;

while( *strings != 0 ) { /* Until reaching null pointer, */
pstring = *strings++; /* get a string pointer, */
do { /* find the length of this string, */
++length; /* using do-while to count the */
} while( *pstring++ != 0 ); /* null terminator. */
}
return length; /* Return total length of all strings */
}

/* Copy a string, including the null terminator, and return a pointer
* to the end of the destination string.
*/
static char *
str0cpy( char *dest, char *source )
{
do { /* use do-while to include null terminator */
*dest++ = *source;
} while( *source++ != 0 );
return dest;
}
```

```
/* Copy an array of strings into an environment string, and return a pointer
* to the end of the environment string.
* `strings' is an array of pointers to strings with a null pointer
* as the last element.
* `envstring' points to the environment string.
*/
static char *
e_strcpy( char *envstring, char *strings[] )
{
while( *strings != 0 ) {
envstring = str0cpy( envstring, *strings );
++strings;
}
return envstring; /* Return end of environment string */
}

/* Run a program, passing it arguments according to the
* GEMDOS Extended Argument Spec.
*
* `childname' is the relative path\filename of the child to execute.
* `args' is an array of pointers to strings to be used as arguments
* to the child. The last array element must be a null pointer.
* `environ' is a global array of pointers to strings
* which make up the caller's environment.
*/
long
execv( char *childname, char *args[] )
{
long envsize, ret;
char *parg, *penvargs, *childenv, *pchildenv;
short lentail;
char argch, tail[128], *ptail;

argch = *penvargs++;
if( argch == 0 ) {
*ptail++ = ' ';
} else {
*ptail++ = argch;
}
}
/* terminate command tail and validate ARGV */
*ptail = 0;
tail[0] = 127;
/*
* Execute child, returning the return code from Pexec()
*/
ret = Pexec( 0, childname, tail, childenv );
Mfree( childenv );
return ret;
}
/* End of execv() example code */
```

Implementation: Prenatal Responsibilities

A program's startup code must handle getting extended arguments out of the environment. The startup code should get the basepage pointer off the stack, then get the environment pointer from the basepage, and search the environment for "ARGV=". If "ARGV=" is found, the command line length byte in the basepage is checked. If the command line length byte is 127, then the arguments in the environment are valid. The first argument begins after the first null following the "ARGV=". It is important not to assume that the null follows immediately after the "ARGV=", because some implementations may assign a value to the ARGV environment variable. After setting up an array of pointers to the arguments, the startup code should set the 'A' of the "ARGV" variable to null, thus separating the environment from the argument strings (remember: a double null terminates the environment).

Here is some example C startup code which shows how a child could look for arguments in its environment:

```
* ARGSTART.S - example C startup code
* using GEMDOS Extended Argument Specification
* ================================================================
* 890910 kbad

* --- release unused memory
sub.l a5,a1 ; size to keep
move.l a1,-(sp)
move.l a5,-(sp) ; base of block to shrink
pea $4a0000 ; Mshrink fn code + junk word of 0
trap #1
lea 12(sp),sp ; pop args
```

```
*
* Everything beyond here depends on implementation.
* At this point, _environ points to envp[], _argvecs points to argv[],
* and _stklimit points to the end of the argv array. Thus argc can
* be calculated as ((_stklimit-_argvecs)/4)-1.
* _main could be invoked as follows:
*
move.l a5,-(sp) ; basepage
move.l _environ,-(sp) ; envp[]
move.l _argvecs,-(sp) ; argv[]
move.l _stklimit,d0 ; 4 bytes past end of argv[]
sub.l (sp),d0 ; (argc+1) * sizeof( char * )
asr.l #2,d0 ; argc+1
subq #1,d0 ; argc
move d0,-(sp)
jsr _main ; call mainline
lea 14(sp),sp ; pop args
```

A Final Note

This specification was formulated with careful deliberation, and with input from several companies and developers who have created development tools for GEMDOS. The Mark Williams extended argument passing scheme was the main influence for this specification, because it has been in use, and supported by Mark Williams and other companies for several years. This specification is very similar to the Mark Williams scheme, with the following important exceptions:

1) Under the specification, the arguments after the ARGV environment variable may be validated by checking the command tail length byte. The Mark Williams execve() library function uses the command tail length byte as a telltale, but it is not checked by the crts0 startup code. This validation is important for the reasons mentioned in the Rationale section above.

2) The specification allows the ARGV environment variable to take on any value. Mark Williams uses the value of ARGV as an iovector, which is described in the Mark Williams documentation. The iovector should no longer be needed, as its primary purpose was to simplify the MWC implementation of the C library function isatty().

3) Some versions of the MWC startup code do not require the ARGV= to have an `='. Because ARGV is an actual environment variable in the specification, the equals character is required.

Why don't we have a propper standard, one of the problems is that
Ataries HDX standard came out far to late.
So why don't all the other Atari developers come up with one
common standard.
Is it not posible to follow the MS-DOS standard, as our disks are
based on that standard..
It would only take a small patch program to fixup the none standard
disk partitions, and for the other developers to fixup there Booters,
or is this to simple a task.

Also are BIG partition standard ?.

I'm trying to get the Net TCP/IP program running on my ST over a dialup line. So far, I can't get my machine talking with the machine I call. I can get the modem to call the local dialup just fine, and a modem connection is established--however, the needed "link" is never established and I'm left without an IP address--thus, the program is virtually useless to me right now.

Some general info: I got the programs from wuarchive.wustl.edu. I'm using Merit dialups (MichNet--the network linking the universities within Michigan). The docfile is by Howard Chu (are you listening?).

Has anyone been able to get Net running on their ST and been successful in telnetting and ftp'ing with their ST? I'd appreciate any help I can get in setting up this program. (It _is_ possible for this to work--I've set up a similar program on a friend's PC.) Thanks.

Well, there's not point in adopting yet another standard now. Atari has
released the details of their standard for adding partitions and for
creating large (big GEM - BGM) partitions. Registered developers can get
this document right now. The new driver comes with all TTs so we might as
well use its standard.

Perhaps they don't want the two formats to be mixed up by users.
Anyway, the two points you made are two of the reasons I wrote my own
driver. Especially (1) is extremely annoying.

I don't quite see your problem. I use emacs 18.55 for ST by E. Roeder
that came in comp.binaries.atari.st (the second distribution I think).
It includes the file atari.el that makes keypad.el work for the ST. It
simply maps a lot of key sequences of the type ESC # <some ascii> to
the sequences used by keypad. I think the conversion from raw keycodes
to ESC # <?> is done by emacs itself (?).

It simply works! atari.el and keypad.el are loaded by the init-file
for temacs that came with the distribution. I'm sure about that,
because when I made xemacs I didn't know anything of keypad.el or
atari.el ...

BTW: mouse-support works too.

2304. ORIGAMI folding editor 1.5.8(beta) source available for FTP

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-10 14:43:11 UTC
From: michaels@messua.informatik.rwth-aachen.de
Message-ID: <michaels.673886591@messua>
Source record: 48199

I have posted this some days ago, but it seems it did not make its way ...

The new version 1.5.8 (beta) of Origami is finished. Origami is a folding editor similar to the TDS editor. (Some PC users call it an outline editor.) It's a little bit difficult to explain the principles of folding editors here, but there are enough explanations in the documentation. Origami runs on MINIX 1.5, SunOS 4.1. and on the Atari ST. The source is available for anonymous FTP from:
Server: ftp.thp.uni-koeln.de [134.95.64.1]

Path: minix/beta-test
Files: origami.tar.Z (13-bit compressed tar archive)

If you detect any bugs in the TOS code, please send mail ONLY to Michael Haardt. He heads beta-testing and would like to see any mails concerning it. He will forward a copy of TOS specific mails to me.

Send mail to:
mhaardt@ftp.thp.uni-koeln.de
DO NOT USE THE ADDRESS IN THE HEADER !

You will probably find mistakes (wrong spelled or wrong grammar) in the documentation. Correcting such mistakes would be nice (cdiffs!). The Origami documentation can be formatted with nroff or MROFF.

The beta-test phase will end in June. I will post Origami to comp.binaries.atari.st then. I will not post any binaries until the beta test ends. I will not send sources or binaries by mail (I have to pay for mail, even incoming).

In order to compile ORIGAMI on the ST, you will need Turbo C 2.0 and some utility to convert LF to CR/LF (all source files are in UN*X format, which is not recognized by TC :-( )

From: heavy@zip.eecs.umich.edu
Message-ID: <1991May10.190549.1252@zip.eecs.umich.edu>
Source record: 48197

I am using GNU C, and I was just wondering what is the
difference between Fopen() [not fopen()] and open()?
Are the file descriptors they return totally different?
The reason I am asking, is when the new Flock() function
is implemented for networking, will we HAVE to use Fopen()
or can we still use open()?

>Or is this a dumb question ?

Well, since the Syquest is a SCSI device, and since the ICD host adaptor
supports the Syquest, you would be even cheaper off by purchasing a bare SQ-555
mechanism and hooking it to the ICD. Then it could be used in both Mac and
ST modes. Given that you can get the mech cheaper than a finished Mac product
(which I would assume is true), this would be the more cost effective way
to go. Alternately, you could buy the Mac unit, open it up, take off the
25pin SCSI cable, put on a 50pin, stick an ICD in there, and away you go. I
am unsure if an adaptor exists, but the cables are so cheap that replacement
would probably be easier (and you would then not have the adaptor connection
to worry about). This is assuming that there is no Mac specific circuitry
or boards in a finished Mac drive of this type (I don't think there are, just
a weird 25pin cable). Of course, the SQ-555 mech uses a standard 50pin SCSI.

Hello!

Anyone out there want to sell me thier GCR for $180? Without the ROMS
of course, as I have my own ROMS.

Wing some mail for some easy money.

I don't think you understood what I was on about, are you stating that we have to upgrade all our Programs and Hard Disk just because of the 'TT'.
The Supra standard was here far before the HDX one,
From what I have read ICD's booter is claimed to be the fastes,
I have seen boot problems with the HDX software, that where fixed by replacing the booter.
Also what states the Ataries Booter is the best..?
I don't think you should be rail roaded in what Atari gives you, I believe in freedom of choice, and not this dogmatic attitude that Atari gives you.

Does this actually work? I have a Syquest drive and would be very interested in
transferring stuff back and forth from Macs (since it seems that the Mac is the computer-that-I-must-have-on-my-desk-to-be-cool here at UT)

I would think that the disk formats would be different, since Apple tends to want to keep thinks like that to themselves, but if Syquest has a proprietary format that they use for their drive, it seems as if that wouldn't get in the way.

Anyone have experience with the Syquest ST-> Mac and back? Care to share some tips?

As strange as it may seem, Roland provides exactly the same cables to
connect their GK-2 Guitar Synthesizer pickup to their GR-50 Guitar
Synthesizer. I'm sure you can get "replacements" from a Roland
Dealer. The Roland cables are a bit longer, too.

I think you might have missed the earlier part of the discussion - for this
to work you would have to have a Spectre 128 and Macintosh ROMS (in other
words, you could read a Mac-formatted syquest cartridge on the ST, but only
if you were running Macintosh emulation on the ST at the time.)

2316. Traps on Resolution Change

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-12 02:41:16 UTC
From: cmedley@wam.umd.edu
Message-ID: <1991May12.024116.26326@wam.umd.edu>
Source record: 48204

I have been working on what I hope to be a commercial product for quite some time, and what it does, running as an accessory, is steal the TRAP #5 vector. I have often thought about making the TRAP #5 code an AUTO .PRG, but decided against it for the sake of simplicity for the user.

What it boils down to is that this TRAP #5 code needs to know if the user has changed resolutions from "Set Preferences" on the desktop. Since all of my code is legal under GEM (in fact, it counts on GEM!) I don't want to use any dangerous hacks. However, I've tried several methods and none work realiably (i.e., checking for new sizes of the desktop window when about to install a new trap handler, checking to see if the TRAP #5 is currently owned by me, etc...). Apparently, one source of my problem is that on a change in the resolution, the ST does do a warm boot, but it does not affect system vectors, like the various TRAP pointers or the hard drive vectors, etc... And my accessory needs to know when the accessories are being flushed so it can clear out, and when the system reloads ACCs, it can reinstall on the TRAP #5.

Any help is appreciated.

I would like to thank all of you that responded with information and help about my questions regarding Spectre.

Well, now onto the other emulator that's supposedly worth having--
Super Charger:

1. Is it _really_ four times faster than an XT?
2. How much memory does it leave you once in IBM mode, with/without Windows?
3. What problems are there with monitors (or any other external hardware such as printers, hard drives, mice, modems, etc.)?

Any help with these questions and any other information would be greatly appreciated.

I know that Dave Small's Spectre now supports the Syquest 44mb cartridges.
Thus, if you are in Spectre mode, you can use them. I would think it very
unlikely that the disks would work while in ST mode, as the Mac hard disk
protocol is just as weird at their floppy protocol.

Suppose I have a Megafile 44 with a Quantum 105 connected to SCSI
controller in the M44 attached to a Mega 4 ST computer.

Can I use Atari HD tools to format the Quantum and/or the cartridges of the
M44?

actually we already have this configuration but we had great difficulty in
getting it to work, had to use ICD tools to format the Quantum.
The HD are know working with AHDI 3.01 as driver
but we still have the following problems:

- we cannot M44 cartridges with HDX 3.02
- On poweron off the system it takes several boot cycles before the HD's are
recognized.
After that everything works fine.

Does anybody knows a solution to our problems?
It should be possible to attach a SCSI drive to the internal SCSI controller
of the Megafile 44, shouldn't it?
(if possibly please reply by email, I can post the solution later)

Harold van Aalderen (hvaalde@cs.vu.nl) and his brother.

Is Punt_aes called by TOS when the actual change from medium to low resolution is done? I am curious because it could help me in solving my problem with handling vectors during the change in resolution from "Set Preferences" and I've always wondered why punt_aes was still included in the ROM versions of TOS. Atari ST Internals (Abacus) never really mentioned any good uses for punt_aes.

2322. WANTED ALIVE: MISSING HD PARTITION!

Newsgroup: comp.sys.atari.st.tech

From: jensend1@yvax.byu.edu
Message-ID: <2309jensend1@yvax.byu.edu>
Source record: 48219

I left my Atari ST running while I was gone for about an hour - it was supposed to finish moving about 400 files from one partition of the hard drive to another while I was gone. I was using the Universal Item Selector for the operation. When I came back, everything seemed okay, but when I later tried to access a different partition, it had disappeared from the list of available drives in the item selector! Now when I try to open the drive D: partition from the desktop, it says the partition does not exist...
Here's the quirk - I have AT Speed installed, and it reads the D: partition just fine. All the files are there, it can read the directory, et cetera. Only the ST has any problem. Even worse, I'm using HotWire as a shell for the ST, and it can still run programs from the D: partition. I just can't do any file manipulation on it.
I'm about ready to reformat the drive and start over. Before I do that, does anyone know what the problem is? Can it be fixed without reformatting? I'm not looking forward to formatting a whole bunch of floppies to 720K just so I can back up the D: partition with a PC backup program. Your ideas would be helpful.

Thanks!

M.U.L.E. was an excellent game for the Atari 8-bits which appeared a while ago. It was more of a simulation of market systems and economic principles, actually, but that didn't mean it wasn't a hell of a lot of fun. As far as I know, it has not appeared in a ST version.

M.U.L.E. and Seven Cities of Gold are the two programs I miss most from the 8-bit days. If anybody knows of ST versions of them, please let me know.

I think they were both put out by Electronic Arts, but I could be wrong.

Thanks,

Todd

From: tdrga@ccwf.cc.utexas.edu
Message-ID: <48901@ut-emx.uucp>
Source record: 48217

Has anyone out there mounted their ST in a different case or housing? I am thinking about putting mine in a 19" rackmount (like they use for audio effects processors, etc.) unit. Since I have a 1040STF, I'd have to detach the keyboard, move the disk drive to the front, and rearrange stuff internally. How difficult is this project? How dangerous? Please note that I don't plan on doing anything that involves sawing circuit boards in half or even modifying the electronics at all beyond what is necessary to detach the keyboard or attach a Mega keyboard.

I am also thinking abotu rackmounting my modem and HD (Syquest). My vision for this project is to have a rolling rackmount unit with the computer and modem and HD which is sturdy enough to transport easily (i.e. unplug power, monitor, and phone cables and then roll into the truck)

Any suggestions, names of suppliers of stuff I would need, better ways to proceed?

Am I just a fool for thinking I can do this?

Thanks,

Todd

This is because there IS no use for Puntaes(). All it does is a warm boot
without GEM IF AND ONLY IF the OS is in RAM.

By the way: there is no legal method for accessories to change vectors.
Thins like that belong into TSRs in the auto folder.

>By the way: there is no legal method for accessories to change vectors.
>Thins like that belong into TSRs in the auto folder.

That's why I'm looking for a officially approved way to intercept Trap #2.
There seems to be no easy way to do this with an AUTO folder program -
AES overwrites any changes, and so you have to write a TSR that waits
for AES to come up and then re-vectors trap #2. The tricky part of this
is waiting for the AES - how can you tell for sure?

Because of this problem, I still have one accessory that re-vectors
trap #2 - it's just much easier and seemed to be OK to me because
this way I can be sure that AES has been started when my accessory comes up.
If someone could show me a legal way for re-vectoring trap #2 in the
AUTO folder, I could get rid of this accessory.

I once put my 520ST into a p-clone case. I had to detach the keyboard.
It worked fine and I was able to put my diskdrive in the slot in the
case. The problem I ran into was with the keybard. It seems that there
are 17 lines to the keyboard. I got some trunk wire I used to install
alarms with and it was 20 conductor cable. I located a 17 pin connector
(it was hard at the time!) and I soldered the wires from the trunk line
to the connectors (one on each end). Then I just left my keyboard in
the old 520's case, and connect the cable. But, the cable was very
stiff as it was 20 conductor and my keyboard would not stay were I
wanted it because it was so light...

My question is: All all 17 wires need??

2329. GNU Make troubles: 2 bombs!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-13 17:18:35 UTC
From: ralph@laas.fr
Message-ID: <RALPH.91May13191835@orion.laas.fr>
Source record: 48222
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

I am trying to use GNU Make in order to control a LaTeX document.
This is GNU make v. 3.54 that comes off of atari.archive. The same
Makefile works on my Sun SPARC, but gives 2 bombs on my Mega 4 ST.
The Makefile replaces .SUFFIXES to be LaTex/TeX specific. It also
uses sub-directories:

```
PARAGRAPHS = $(patsubst %,$(DIR_P)/%.tex, $(PARAGRAPHS_LIST))
```

The rule that GNU make has trouble with seems to be the following:

```
%.bbl : %.bib $(DIR_P)/%.tex
-bibtex $*
if egrep -s "^(There were .* error messages)$$" $*.blg ; then \
touch $< ; fi
```

$DIR_P has the value "acm". When GNU make is run with -d it sees that
it should check in the subdirectory. But when wanting to do the
implicit dependencies for foobar.bbl, which are foobar.bib and
acm/foobar.tex, it tries also to look for either acm/SCCS/foobar.tex
or acm/RCS/foobar.tex. Immediately: 2 bombs! Earlier, it checked for
SCCS/foobar.tex and RCS/foobar.tex and coninued without aborting.

The problem might be the double directory structure. Has anybody else
used GNUMAKE for LaTeX and friends? Also, this GNUMAKE came with GCC
1.35 or 1.36. Maybe a more recent version is necessary.

Thanks to all,

>Anyone have any clues or fixes for this?
>

It's at atari.archive, like PATCH302 (the NeoDesk patch) was. I don't know
where Jeff Weiner put it. Jeff? :^)

I tried using SIMMFIX, but the computer would rarely recognize it when
it would run. I would get a TOS ERROR 35 when run from the desktop, or
nothing when it was run from the AUTO folder. Therefore, I was using
2megs until I upgraded to 4 recently. The executable file is only
248 BYTES long, but I don't think that would be a basis for it not
running. Another disadvantage with the program is that it requires a
warmboot to reconfigure the memory.

Don't reformat the drive. As long as HotWire can still run the programs on
Drive D:, it seems everything should be intact.

This may sound like a dumb question, but I'll ask it anyway. :^) Have
you tried manipulating (copying, etc.) files with the desktop, or
another file manipulation program? I use UIS III as well, and I don't
understand the problem it would have with Drive D:.

BTW, what do you see in UIS's drive listing? A,B,C,E,F, etc?

I recently acquired a TT030, but unfortunately, my beloved
19" Moniterm will not work with it, so I must sell it to
get a large screen TT monitor.

The Moniterm is 1280 x 960,
it requires a Mega,
and TOS 1.4.
(graphics card included)

Asking $1000, list price $2000...reasonable offers
accepted, but I reserve the right to refuse any offer.

Shipping not included.

For anyone wondering, trust me, it is worth it, I paid a lot
more and still thought it was worth it, I can't live without
it now, that is why I want one for my TT...

2334. TT problem + ST's for sale

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-14 05:22:20 UTC
From: apalmer@pyrtech.pyramid.com
Message-ID: <155368@pyramid.pyramid.com>
Source record: 48220
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

This last weekend, I purchased a TT. After reading on c.s.a.st that the latest tos was 3.05, I was shocked to discover I had tos 3.01. The TT came in a unopened box that the dealer received about 12 days ago. Why the hell is the dos over 6 months old. If somebody from Atari reads this, I would appreciate a responce. Is there a way I can get an upgrade?

The reason for my concern is problems I'm having with file systems. Hanging off the dma port, I have 2 Quantum pro 80 and 1 Micro 1375. I have had three partitions develop directories that point to themselfs. This prevents show info from working. The directories appears to be infinitely deep. The drives use 1 ICD and 1 Supra hosts. (ICD->Pro80+Micro1375 Supra->Pro80)

I'm selling two of my old systems. I would like to sell them as systems, but I will consider all offers.

System 1

-1040STf w/tos1.4 + 2.5 megs (board can be upgraded to 4 megs <$100)
-SM124 mono monitor
-Quantun Pro80S 84meg 3 1/5 drive in Supra case
-Spectre 128 w/Mac roms - Macintosh Plus emulator
-Star SG10 printer
-IMG Scan image scanner
-LDW Basic compiler
-MicroLawyer
-DC Desktop
-Beckemeyer Hard Disk Toolkit
-Supra hard disk utilities
-Why Wait? floppy & hard disk cache + print spooler + ram disk
-SGS Switch program switcher
-.ACCess CLI
-Micro Kitchen Companion recipes on disk

All software has original docs. I will leave shareware and public domain on the hard drive. This would be a great system for someone thinking about buying a Mac. I'm asking $1200 for the complete system. If you have concern about buying a used harddrive, I will swap the new 50meg TT mech for the Quantun and knock $100 off the price.

System 2

-520ST w/tos1.4 + 1 meg + Z-Time clock chip + Mega keyboard
-CCC Learning Station case with 2 DS floppy drives
-SC1224 color monitor
-Rixon T212A 1200 baud modem

-ST Talk Professional telecommunications software
-Neo Desk
-pc-ditto 3.0 - IBM emulator
-Degas graphic arts system
-UMS Universal Military Simulator
-Dive Bomber
-All Aboard!
-Space Cutter
-Micro League Wrestling
-GATO
-Devon Aire

The CCC case is a metal case that holds two Atari floppy drives plus power supplies for the computer and drives. Everything, including the monitor, plugs into an internal power strip with an external power switch. The drives have the cheap mechanisms replaced with Epson mechs. I'm asking $600 for this system.

I also have about 10 Mega keyboards that I would like to sell. These are just the bare bones keyboards. They are a direct replacement for the keyboard in the original 520 without the internal floppy. I'm asking $40 each for the keyboards or 3 for $100.

If the above systems don't match your needs, I would be willing to rearrange the hardware and software to meet your needs. Just make an offer. All the hardware is in very good condition.

If you are interested in any of the above, please reply with e-mail or call me at (408) 992-0131. If I'm not home, leave a message and I will get back to you.

thanks,
al

No. If you connect the mouse and the joystick direktly to the keyboard, only 5 connection to the cpu are required. If you drop the keyboard reset, only 4 lines are needed. I detached my keyboard some time ago, so it would be hard for me to find the pinout in my docus. But if nobody else has the info, I could search it in my archive. ;-)

From: kawakami@bigbang.Berkeley.EDU
Message-ID: <42140@ucbvax.BERKELEY.EDU>
Source record: 48226

Q: are all 17 wires needed from the 520 ST keyboard to the console?

A: No, only six or seven are. The remainder are to connect the mouse
to the keyboard controller. If you can trace these wires out, you
can build a mouse port and joystick port onto a small board and connect
them that way.'

ATDT 96427400

Comment:
I don't think that moving the keyboard away this way is so hot after
all. I think a better alternative is to get an IBM keyboard interface.
The PC keyboards are nicer, and have coily cables.
I think such an interface would be easy to build: 2 uarts and some
control logic. The problem is, I don't know the PC keyboard's baud
rate.

Q: does anyone out there know the PC keyboard baud rate?

Source record: 48227

<This is in reference to the discussion about how the AES reinstalls TRAP #2 and all...>

I'm sure there has to be a fairly reliable way to pull off intercepting the TRAP #2 vector. It may require the method of re-installing it whenever the AES tries to change it back and all, which is about as easy from an AUTO program as it would be from an .ACC. The reason I think this has to be workable is that the program Form_Doit from Dan Wilga is doing it, and that is installable from AUTO.

Incidentally, I understand that the new Atari Control Panel has hooks into the AES for a modified form_do call that doesn't "lock up" the system. Does anyone know if it is legally patching into TRAP #2 or if it is actually a new form_do handler in the ROMs?

I think that the keyboard only needs 3 or 4 wires max. The rest of
the wires go right straight to the mouse/joystick conectors.
If you place these connectors with the keyboard unit that cuts your
wire count down to where a PC keyboard cable works fine. I know,
I've done it.

2340. Bug in Overscan software.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-14 19:35:47 UTC
From: micro@imada.ou.dk
Message-ID: <1991May14.193547.29278@imada.ou.dk>
Source record: 48229

There have been some talk about Overscan here lately, that reminded me
that I found 2 bugs in the driver software. The bugs are in the same 10
lines of code, and they are kind of strange!
The scene is the following:
AES initializes itself and opens a Screen workstation. Overscan sits in
the AES/VDI trap and checks for that call, and let it run, after it have
run Overscan initilizes the LineA varibales, (in Do.something).
At this point Overscan wants to change the variables in your WorkOut array,
this is where things go wrong

1. (this is the worst) it puts the width and height of the screen into
WorkOut[0] and WorkOut[1] instead of the highest addressable cell (width-1
and Height-1).

2. it tells that you have 200 colors in color mode, and not $200(or 512).

Note that these errors overrides the values put into the LineA varibales
that otherwise are good enough.

Then why don't I release my version?
- Overscan is Commercial now so I don't know if it's legal. Also my version
have been hacked so much that it probaly have even more errors.
(I have taken the illigal fidling with the allocated memory lists out and
removed compability with prehistoric TOSes) - so you probaly don't want it
anyway...
How can we fix this problem - I guess that Karsten will tell us that he have
a fix (called autoswitch Overscan).

Klaus, micro@imada.ou.dk

2341. Reading a Disk Sector

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-14 22:36:33 UTC
From: ccs004@bambam.Ucdavis.EDU
Message-ID: <12948@aggie.ucdavis.edu>
Source record: 48232

Hola,

I need to know how to read a sector from a disk in ST-Basic. I have
the new version of basic that came with my 1040 STE. I used to be able
to read sectors with a small assemble routine that I used with that Call
command. This know longer work though because the new version has
made all integers 32-bits long, and the assembly routine expects paramaters
to be passed in 16-bit integers. The new version of basic has built in
commands to call different OS routines. I don't have a reference book
though. Can anybody give me the command to read and write sectors or
a routine to do it. Thanks.

Nick Adami

2342. STe Internals

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-15 03:24:04 UTC
From: kiki@uhunix1.uhcc.Hawaii.Edu
Message-ID: <13023@uhccux.uhcc.Hawaii.Edu>
Source record: 48233

These interesting chips were found in my STe:

[From motherboard labeled GX-211 VO 4990]

pins package label * = soldered
---
a) 144 quad flat pack C300589-001, c. 1988, -19, J9030 *

b) 84 " plcc C301712-001, c. 1990, -31 I60608-01, 9029EBB

c) 68 " plcc C101643, c. 1989, -31 I60611-01, 9033ETB

d) 68 " plcc MC68000FN8, 2C91E, QEYX9025

e) 48 dip MK68901N-04, D9028 *

f) 40 dip C398739-001A, c. 1990, -31 I60511-01, 9031PCA *

g) 40 dip Yamaha, YM2149F, 9039 GAGG

The chips with a 'C' prefix (a, b, c, and f) are designed by Atari. Dr. Tsuji of Waseda Univ. informed me that they were GALs (gate-array logic) and were fabricated in Japan. The WD 1772 floppy controller is located under the disk drive (Sony drive w/ 5V only power input), so there is very little room for an alternate board to plug into the 28-pin socket. The Yamaha sound chip is socketed for some reason, while the 2 TOS ROMs are soldered.

Information about the many of the Atari STe chips is not available to the general public, so I have some questions that might be answered here.

1) The old MMU and GLUE are supposedly integrated into the MLUE. Since the former chips had 68 pins apiece, what, if any, enhancements does the MLUE have? Since the new MLUE has about 12 extra pins (144 - (2*68) + unused ROM selects), did the designers create an additional memory multiplex address line so that 4 MB SIMMs could be used? Who has info on the GAL chips?

2) Reading/writing the area of memory between $400000 (end of 4MB DRAM memory) and $CFFFFF causes a bus error, however addressing $D00000 (start of 13MB) to $DFFFFF seems to be OK. Is this memory protection specfic to the STe? Although a local dealer claimed the new Mega STe has the same addressing scheme, it would seem that it would support the entire 16MB space. So can anyone verify that the Mega STe uses a different MLUE and has an extended addressing capability?

3) So far people have informed me that the Atari developer documentation isn't a good value, even at $125. What are the alternatives??? Supposedly TOS was developed in Germany and the chips made in Japan, so all the docs lack any cohesion. What will happen when Atari brings out a system designed

in Britain by an Indian engineer with a floppy chip from Israel, monitors from Korea and Netherlands, custom chips from Japan, German TOS, a Unix GUI from France and manufactures it in Taiwan. Then will it be voted number one again in Hong Kong?

I received the developer kit registration form and it requires that all information received from Atari not be disclosed. In fact, it prohibits you from disclosing the fact that you are prohibited from disclosing facts. If you disagree with this policy, please send mail to Bob Rehbock, Director of Technical Services, c/o Atari Corp, 1196 Borregas Ave, Sunnyvale, CA 94088-3427.

I can understand putting a restriction on the divulgence of Atari's prospective products and plans, but all their current systems should have complete and open documentation. If Atari dominated the industry, then their stance might be understandable, but the trend is toward open systems and I feel it would be to their benefit if they would disseminate their documentation without excess- ive restrictions.

Jack

P.S. Let's go TEAM Motorola!!!

I read in one of the on-line magazines a couple of months ago that Jim Allen
had developed a 14meg upgrade for the STe and a 10meg upgrade for the MegaSTe.
I couldn't understand the difference, since I would expect the MegaSTe to
be able to be upgraded with more RAM, but I haven't heard anything since.
Perhaps these are related.

Hi,

I'm new to this group so I apologize if this is a common question.

I have a 20 Meg MFM hard disk designed to connect inside a pc or mac
with the correct interface. Is there a company that makes MFM or RLL
interfaces for the Atari ST?

Thanks,

It seems that you ment the Fopen of the atari system calls (the Fopen
of atari Bios). Most C compilers (GNU included) used on ST machines
are using Fopen() for open() and fopen(). I think therfor
it is no problem at all using open() or fopen().

I don't think I said all chips inside STe were made in Japan. The famous new DMA chips are made in Taiwan. The GALs in there are custom made chips with relatively few transistors. Not to be confused with ordinary GALs which can be treated by hobbyists like EPROMs.

2347. Legality of Shareware

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-15 13:00:52 UTC
From: glens@natinst.com
Message-ID: <23241@natinst.natinst.com>
Source record: 48231

I am not sure if this is the best group to ask this question but
after looking through all the groups available to me I chose this one. So
here goes ...

I am writing a replica of a major arcade hit. Will I be able to
make it Shareware without getting in any sort of legal troubles. If not
can I make it Public Domain without getting in trouble?

I have seen other replicas of older games both as Shareware and
Public Domain but I am hesitant because of the size and nature of the
company which produced the original that I am replicating.

Thanks,

My opinions do not necessarily reflect those of my employer and probably are
exact opposites.

2348. G++ bug with headerfiles - a solution?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-15 13:39:59 UTC
From: ZVD007@DMSWWU1C.BITNET
Message-ID: <91135.144341ZVD007@DMSWWU1C.BITNET>
Source record: 48237

I've read in this newsgroup several times, that people have problems with
g++ when they use headerfiles. So have I. I think the problem (g++ doesnt find
the c++ headerfiles, but the c headerfiles) is that gcc_cpp does not
search on the G++INC-Path; one can proof this by listing the binary and looking
for a string G++INC, its not there, but there is a string GNUINC.
So, if there is anybody having the sources of the preprocessor, please
look for this and let me know if I'm right.

U.Kuehn

p.s.: When compiling wih g++, its better to use -I$G++INC than to use
#include with the right path, because you have then to patch all the
c++ headerfiles when they use other c++ headerfiles.

Well, my main point was that you don't have to write everything _yourself_.
One can use quite a bit of existing drivers.

Is somebody out there already working on a device driver of his own ?

I am having a dificult time finding someone who has installed
an OVERSCAN switch on a 1040STf. I know it can be done, and
I'm looking for specifics.

My ST' motherboard has its ram located under the Motherboard,
and Its modle number is ST PCB.P.N.C070789 REV.XXX

PLEASE!! Help!!

I have installed a multiSync monitor and I want to try and
max out the resolution to see how it looks.

Any information is greatly appriciated.

A few days ago I was asked by some readers of this group to send
a program of mine, DabbelFeature, to atari.archive. I've done so now,
and you can ftp it from there. (Look for it under newitems or diskutils.)

DabbelFeature is meant to redirect drive accesses. It can, for example,
redirect every access to drive C to drive A. Hope it will be useful for
you.

Enjoy,

Don't forget the Delta Modul. It is the most powerful AT-emulator with it's 16MHz 386sx for the ST available. Yes, it is really available, from certain dealers in Germany. 1198,- DM.

And Omega, the maker of Delta Modul has released a cheap but very powerful graphic card for ST (/TT, dont know). Frequencies from 66 to 71Hz, and if I remember correctly, 1280x960 with 16/256 colors in about 70Hz is the maximum. And it costs way under 700,- Deutche Mark!!!

That's interesting, because I was thinking that Atari wouldn't be allocating any more development time to the 1040 STe machines, so they decided to solder the ROMs. Although in the March/April Atari Explorer, Greg Pratt said that a multi-tasking TOS was due soon, so I suppose it will require a ROM upgrade?

I was a little happy that the Yamaha sound chip was socketed because they make a similar chip, the YM-2203, with enhanced capabilities (FM sound, 13-bit D/A, prog. multiple modulation and feedback) that is software compatible and nearly pin compatible. If there is interest, I can post more specs later.

Atari packed a lot of value in the STe models and I think the people of Hong Kong were right when they voted it the computer of the decade.

>I read in one of the on-line magazines a couple of months ago that Jim Allen
>had developed a 14meg upgrade for the STe and a 10meg upgrade for the MegaSTe.
>I couldn't understand the difference, since I would expect the MegaSTe to
>be able to be upgraded with more RAM, but I haven't heard anything since.
>Perhaps these are related.

The 14MB upgrade sounds like inserting 4 4MB SIMMs into the STe SIMM socket, with the last 2MB lost because of the ROM address space which begins at $E00000 (start of 14MB). The 10MB version sounds like 2 4MB and 2 1MB SIMMs, but I'm not sure why it would be particular to the Mega STe.

From: gt1448b@prism.gatech.EDU
Message-ID: <29126@hydra.gatech.EDU>
Source record: 48095

I seem to remember seeing some source code for an auto folder program
that installed a custom trap #2 which required that a custom trap #13
was installed. It looked for BIOS #5 (set exception vector) to see if
it was setting the GEM critical error vector found at system variable
$404. If the trap #2 was not the custom trap #2, then it reinstalled
the custom trap #2.

> TWO WEEKS UNTIL GRADUATION!!

Well the latest STE's here in NZ. now have Brass inserts (3) for the
Screws that hold down the Main PCB. these can be seen if you turn over
the machine, as they come though the bottom, also with a newer type
Epson disk drive, now has a blue plasic cover over the motor, this
drive will give you 84 tracks.

The Sony Drive will give you 82 track and the Mitsumi will give you 81.
The early Epson dives can have problems with a PC conector to drive PCB,
(Drive will not stop), just remove this connector and clean with contact
cleaner, problem was intermitent index pulses.

I don't like any of the newer Epson drives, they use a rack and pinion
mechanism to move the head, this can cause hairs to get caught in the
rack and pinion gears.

showdvi is quite good (colour and mono) from terminator whoops atari.archive!

>I'd also be interested to hear of any PD drawing
>software which will produce encapsulated postscript

If you have got enough memory I think there has been a port of PORTABLE
BITMAP software to the ST, this is PD and takes many input bitmaps
(Degas and .img included) and can convert these to encapsulated
PostScript, if I'm lying about this someone really should do a port of
this utility. Anyhow the portable bitmap stuff is very good even if it
wasn't what was asked for!

I believe the problem is a memory leak somewhere. GNU Make seems to
crash after I use it for a while, and the more memory I have
available, the longer it takes. I haven't really tested this idea out
scientifically, so it should be taken for what it is--pure
speculation. In reality, the problem might be caused by something
completely different.

Hello Klaus,

the actual driver for the autoswitch-overscan is 51! versions away from the
old one released into netland. I found lots of bugs ;-)
The autoswitch feature is about 32 versions old and running very stable. I
ported this feature to some other software, now we have the autoswitch
SM-124 emulator for TT-High and and autoswitch driver for the Reflex 1024
card.

>Then why don't I release my version?
>- Overscan is Commercial now so I don't know if it's legal. Also my version

I made a rather large technical post on the VME capabilities of the MEGA STE and TT machine a while back.

However, a german company makes an extended card cage for the TT/MEGA STE and VME cards for graphics and cpu accelerators. It was shown at the last CeBit show, I think.

So yes, you can have more than one card with the addition of an external cage.

However, don't expect to see anything like that here in the US. :(

Nope.

I don't know where this rumour came from, but it's been flying around
for some time now, and I've run into it about 3 times in the past month,
so it's time to start spreading facts.

Nobody should be touching trap #2 on a res change. Think about it for
a minute: if trap #2 got taken every res change how could GDOS possibly
work?

Assemble the following, put it in your auto folder, and change res a
couple dozen times. You'll see that the trap #2 counter in the upper
left corner of the screen keeps on ticking...

```
; TAKE2.S - count trap #2's, even after res change.

trap2vec = $88
_v_bas_ad = $44e

start:
pea take2(pc)
move #$26,-(sp)
trap #14 ; Supexec(take2)
addq #6,sp

clr.w -(sp)
move.l #($100+fin-start),-(sp)
move.w #$31,-(sp)
trap #1 ; Ptermres(0,size)

take2:
lea save2(pc),a0
move.l trap2vec,(a0)+
move.l a0,trap2vec
rts

save2:
dc.l 0
do2:
move.l _v_bas_ad,a0
addq.l #1,(a0)
move.l save2(pc),a0
```

```
jmp (a0)

|I don't think you should be rail roaded in what Atari gives you, I
|believe in freedom of choice, and not this dogmatic attitude that Atari
|gives you.

Precisely. You are free to use whatever hard disk driver software
you desire. If you want to use the Supra software, buy a Supra drive
and use it. If you want to use the ICD software, buy an ICD drive
or host adapter, and enjoy yourself.

Likewise, Atari should be free to choose whether or not to follow
a "standard" created by a third party. Some such standards are hacks,
some are good ideas, some have a core of good ideas with a lot of
extra nonsense that Atari doesn't need in a standard.

The bottom line for us is that it doesn't matter what standard we
decide on, some people will be unhappy with our decisions. That's
something we live with. You can't please all the people all the time.
You can't please all Atari users hardly ever <grin>.

Desk accessories should not steal trap vectors.

This is not to say that lots of DA's (desk accessories should not steal trap vectors) that are already out there don't take vectors, but (desk accessories should not steal trap vectors) it really isn't a recommended thing.

Desk accessories, as we all know, are (desk accessories should not steal trap vectors) accessories, side-liners, assistants, and as such (desk accessories should not steal trap vectors) they don't warrant the same considerations (desk accessories should not steal trap vectors) as main-line applications.

As Julian R. (hi, Julian!) has recently pointed out (desk accessories should not steal trap vectors), things that take vectors really belong in the AUTO folder. TSRs should be the ones (desk accessories should not steal trap vectors) setting up resources like this, and they should use the Cookie Jar to communicate with other programs.

|anyone know if it is legally patching into TRAP #2 or if it is actually a
|new form_do handler in the ROMs?

No hooks, just a library routine that is also available to CPX's, since
they run as little pieces of XControl.

Is it possible/have they already made an accelerator card that uses the buslines available on the VME/Atari (TT/mega)bus slots? Like for instance a 68040 board that takes over the machine (I've seen stuff like that for the Mac and thought you might be able to do the same thing) and delegates the on board cpu as an I/O handler (and other CPU wasting projects). However, I could be mistaken (_I_ don't use 'em, let alone build 'em), but would something like that be possible for the TT? Dave Small has already shown that it's possible for the ST...:)

If the vertical hold is causing you problems when you run a program that
requires 50Hz, there should be an adjustment on the back of your monitor.
One small adjustment should be fine, and you won't have to change it
when you want to go back to 60Hz.

++ I believe the problem is a memory leak somewhere. GNU Make seems to
++ crash after I use it for a while, and the more memory I have
++ available, the longer it takes. I haven't really tested this idea out
++ scientifically, so it should be taken for what it is--pure
++ speculation. In reality, the problem might be caused by something
++ completely different.

I *wondered* whether that was the problem I was getting, I checked ou the operation of GNUMake under Monitor and the problem seemed to be some interaction between the CLI (Edgar Roeder's Bash) and Gnumake and seemed to indicate problems with mshrink.

I recompiled GNUMake for my own purposes, without a number of the search options (.F, etc) and removed the SCCS stuff, leaving in the RCS. I also used a different shell. The problem went away. I didn't follow it up.

Source record: 48113

kbad@atari.UUCP (Ken Badertscher) writes:

>Assemble the following, put it in your auto folder, and change res a
>couple dozen times. You'll see that the trap #2 counter in the upper
>left corner of the screen keeps on ticking...

Yes, it keeps on ticking. But this is not my problem. The last time
I checked I found out the following (at least I thought this was
the case): You can install your own Trap #2 routines in the AUTO
folder. AES or GDOS or whoever changes the vector, but is friendly
enough to jump to the old routine in the Trap #2 vector after it
has done its job. This is why your routine keeps on ticking.
But this also means that I don't have any chance to do
parameter fiddling _before_ AES or VDI do their job unless I wait
for AES to come up, and then install my own Trap #2 handler.

As I'm thinking about it now (sorry for any mistakes, it's been
some months that I thought about it the last time), this is just
the standard problem of installation sequences. It's just that so
many programs like to intercept Trap #2 - this makes it worthwhile
to come up with a general solution for it.

To open another thread of discussion: Allan Pratt mentioned the
possibility of virtual memory support in TOS, including protection
mechanisms. The XBRA standard comes to my mind: To find out if
my own program has already been installed, I have to wander through
other processes' memory. I wonder if this could cause severe
problems in some upcoming VM, multitasking TOS.

Message-ID: <2803@prles2.prl.philips.nl>
Source record: 48117

Woow, I got a message from my local dealer that they
have received the Mega STe finally.
I called up the guy, which wanted to buy my 'old' ST,
sold it and went to the dealer.

Beeeh, they only received the 1M and 2M versions,
and as they provide good service (they simply exchange
computers in case of defects in the first few weeks after
the sale) I do not gonna upgrade it myself...

So, I have to wait another week for the 4M Mega STe.

But I do have some questions:

1. Does it come having the hard disk already formatted?

2. If not formatted, what partitions is the best choice?

3. How do I have to format the hard disk, when I want
one partition for a PC emulator?

4. Are there already PC emulators for the Mega STe?

Thanks.

I am using an Atari 520 STfm with 1 Meg, and Uniterm. As a desk accessory I use Rambuffer to create a 256K Ram disk (H:). The only other resident programs that I use are Butler James (desk accessory) and Pyro. Since I have started using Rambuffer, Uniterm only seems to be able to allocate 5K to system even though I have the buffer set to 256K. I only use 32K for transfers, and very little for everything else. What in the world do I need to do to use all the memory that I want to?

From: markez@csd4.csd.uwm.edu
Message-ID: <12219@uwm.edu>
Source record: 48116

I have a May 1986 SC1224 Color monitor, made by Gold Star in Korea with an apparent power supply problem. I turn it on, get power but no "picture". I opened it up and discovered that all the output voltages on the power supply are exactly half of what they are marked. I THINK it is the 330uf 250V capacitor... (which I have had NO luck finding a replacement part for). The power supply uses a voltage doubler circuit... Have there been problems with these? If I have diagnosed this correctly, where can I get a replacement part? If I haven't, does anyone know what might be wrong?

There is a rack mounted ST clone (without propriety chips) available in
Germany for musicians (so no, you are not a fool). As for doing it
yourself, why not? You may get a suggestion to call Tech-Specialities
and ask about their CPU cases. Don't, the company is bad news. I think
you can buy empty audio cases through the mail (I would try Computer
Shopper). A little drilling and gluing and bam, ST on wheels.

Yes. There are several 50Hz programs for the ST (most of the time, they are the only difference between euro and US versions of games). If you get the demo called finalcut from atari.archive, it includes a program called changehz.prg. Also, there are 50Hz booters, with which you can boot your computer in 50Hz (for autobooting games and demoes). I think there is one on atari.archive also, if not email me.

You can only do this if you have a "recent" SC1224. The GoldStar monitors won't work in both modes unless you fiddle with the adjustment switches in the back. (Do this while the monitor is OFF.) In fact, GoldStar monitors evidently can't be adjusted to work in both modes no matter what you do. People with those monitors are just scr*wed when it comes to scan-rate dependent European software.

My main goal for the project is not to have a rack-mounted ST for music and sampling, but to simply free up the desk space that I have so little of and to put all of my computer stuff in a portable and secure enclosure. Someone mentioned their concerns about mounting a HD in the rackmout. I don't plan on moving the computer when it is in use, so there should be no problems with head crashes, etc.

I have looked into PC magazines to find info from companies who make rackmount and industrial versions of PC-clones. Hopefully they will give me some ideas.

Don't know when I'll get around to doing it, though. Hopefully, within the next couple of months.

We have been using the GoldStar Monitors here in NZ. for many years
without any 50/60HZ problems at all, if they are set up correctly they
will work ok.

How many times do I have to post this? I have one, and it won't work
in both modes. Period. Just because yours does doesn't mean
everyone's will. I think I'm competent enough to adjust the picture so
that after several hours of fiddling on several different occasions I
could get it would work, but NO, mine simply won't do it. And neither
will a friend's SC1224, both with the Atari label, mind you.

If I get my monitor into the state where the picture is "stable"
in both modes, the picture is shifted half way off the screen and
is incredibly grainy. Great.

So what can I say? NOT ALL SC1224's will work in both modes without
the adjustments being every time you want to change scan rates.

If people didn't do brain-damaged things like rely on the scan rate, we
wouldn't have this problem, but since people seem to have the attitude
of "hell, it works on my machine, it must work on everyone else's too."
we're doomed to have this problem 'til the end of time. (Or until
everyone's running their ST's off multisync monitors.)

>Hello Klaus,

>the actual driver for the autoswitch-overscan is 51! versions away from the
>old one released into netland. I found lots of bugs ;-)

I my version I have fixed these :
o a bug that ment that some programs wrote one pixel outside
the screen, have been fixed.
o the software is 68010/20/30/40 clean.
o the software works on TOS 1.4 and __later__! (it don't use
undocumented system variables to enlarge the screen memory
any more!)
o it is now possible to disable Overscan, from within a bad
program (last resort, as it is not possible to tell accs
and the AES about the new screen size).
o it is also possible to enable/disable Overscan from the
desktop (general, because it is possible to init. AES and
accs).
o the hook into VDI now preserves ALL address registers!
o the driver is now 3700 bytes, of which 3000 stays in memory,
(not counting the larger screen (68Kb)).

>The autoswitch feature is about 32 versions old and running very stable. I
>ported this feature to some other software, now we have the autoswitch
>SM-124 emulator for TT-High and and autoswitch driver for the Reflex 1024

How do you tell accs and the AES about the new screen size, I know that you
have a reputation for making some really awsome hooks into TOS/GEM. But
you can't tell accs that the screen size have changed - can you?

>>Then why don't I release my version?
>>- Overscan is Commercial now so I don't know if it's legal. Also my version
>>have been hacked so much that it probaly have even more errors.

It have been running stable for some time though, and a lot have been fixed!

Why don't you check the trap #2 XBRA chain, before you run the
patch routine (in the patch routine)? If you isn't the last, then
remove yourself from the XBRA chain and insert again in the end.
-before the the first non-XBRA routine (hopefully TOS).
(you don't have to search all the chain, but only from the 'link'
address in your XBRA header, this reduces the searching time and
the risk that some fool takes the trap (non-XBRA)).

I feel like saying this one more time : XBRA!!!

>To open another thread of discussion: Allan Pratt mentioned the
>possibility of virtual memory support in TOS, including protection
>mechanisms. The XBRA standard comes to my mind: To find out if
>my own program has already been installed, I have to wander through
>other processes' memory. I wonder if this could cause severe
>problems in some upcoming VM, multitasking TOS.

A TSR is not a process! It is a part of the exception handling system.
I guess that the Supervisor have the right to do anything! But that
programs that run in usermode will have problems if they access outside
the pages that they have been assigned!
Programs that stay resident is special, they have to be in memory at all
times because they are not processes! Normally in VM systems the processes
are assigned addresses that start from some fixed address (fx 0) to implement
"allocate on access"! These two things are conflicting, because TSR's start
their life as a Process!
Somehow the TSR's memory have to be given to the System (so that it become
part of the operating system). Because a TSR have to call the next Exception
handler, all TSR (and therefor Processes) have to be allocated unique
addresses!
And because programs enter and leave Supervisor mode, they have to have
the same address translation table! (or at least the User-address translation
table have to contain a subset of the supervisor mode ditto).

I hope that Atari comes up with some real radical thinking, so that we
can have VM.

2390. How to intercept TOS vectores

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-19 18:54:24 UTC
From: micro@imada.ou.dk
Message-ID: <1991May19.185424.18475@imada.ou.dk>
Source record: 48131

I have collected the following BAD things from the Overscan driver at
atari.archive. I post this in the hope that this can stop BAD things!

- move SR,Dx - the instruction was used to check if the CPU
was in USER or SUPER mode!!! The instruction can be used
to that on all 680x0 cpus, but cpu's later than the 68000
will tell you, that the cpu is in user mode with a PRIVILEGE
VIALTION exception.

- the new 68K cpus put more on the stack when processing an exception
this means that the offsets to parameters from within the trap
dispatchers are diffrend on new (10/20...) cpus. To fix this it is
possible to use the new system variable 'longframe'.

- remember that GEMDOS, XBIOS, BIOS is documented to change
D0-D2/A0-A2, this means that you should be able to use them too,
If is wasn't for TurboC and many other applications, that consider
A2 safe! (use as few registers as possible and don't use D3-D7/
A2-A6)!
AES and the VDI are special! Here you can't even A0 and A1 and
D0 and D1 is used to pass parameters! (Save all registers!)

The next don't have anything thing to do with Overscan:

- Remember to use the XBRA protocol, when taking a vector, there
is nothing to it. Put the following just about the entry point

```
XBRA_ID: DC.B 'XBRA' ; Tell that the XBRA is used.
APPL_ID: DC.B 'name' ; your identifyer (like cookies)
OLD_VEC: DS.L 1 ; Save the old vector here!
entry:
```

- When you use the VDI, then remember to get the handle for the
Screen from the AES, with graf_handle(). It is really painfull
to use a program that don't, when AMCGDOS is installed:
"Your application uses illigal handles!",
SFX_PAK, CAL4.7 (or something) and many DC-utilities comes to
mind.

Do you have any things that you would hope people stopped doing, besides
minding their own business.

```

2391. Using Mac fonts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-19 22:49:34 UTC
From: tdrga@ccwf.cc.utexas.edu
Message-ID: <49233@ut-emx.uucp>
Source record: 48128
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

My questions to the net:

What do I have to do to use some of the Mac fonts that I have found archived on various FTP servers? What program will convert the to GDOS (or other) fonts that I can use? I am interested in using the fonts for DTP and screen fonts.

I am ignorant when it comes to Mac file structure, systems, etc. The doc files for some of the fonts mention things like 'Font DA Mover file' 'suitcase file' 'resource forks' etc. what do these mean *to me* as an Atari user? How easy is it to convert these various file types into something my machine can read/use?

Are there UnBinHex and UnStuffIt programs for the ST or UNIX? Or do I have to find a Mac to unarchive these files? (I have a general idea what BinHex and StuffIt do - they are comparable to uuencode and ARC/LZH, respectively - or is this not the case)

Thanks,

Todd
(E-mail replies if you have to explain something really trivial that I got wrong. Otherwise, post if it is of general interest)

>A long time ago, someone posted here or the info-atari16 digest, that
>they had a modified Dumas' uud, which accepts the multi-part files all
>concatenanted into one stream. Does anyone have this?

Get the file 'uux789.zoo' from atari.archive.umich.edu in the archivers
directory. It contains TOS executables uud.ttp and uue.ttp. It also has
source code for both the encoder and decoder that may be compiled under
GEM, UNIX, and MS-DOS.

The uud will work with multi-part files that are concatenated in order. It
also works if the files are just in the same directory as the first file
provided they are properly named.

There is a doc file included.

I use these programs on my ST and on the UNIX box here. My only 'complaint'
is that sequence checking is only done on the first file of a multi-file set.
However, it hasn't bothered me enough to get me to look at the sources to fix
it. 8^)

I imagine that the reason for a smaller maximal memory upgrade for MegaSTEs
is that the VME bus requires some address space. I don't know if 4 Meg is
available on the VME bus or not, but that might explain it. Can't put RAM
where the bus is on the memory map!

2395. Yamaha FM-SSG music chip

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-20 10:09:37 UTC
From: kiki@uhunix1.uhcc.Hawaii.Edu
Message-ID: <13123@uhccux.uhcc.Hawaii.Edu>
Source record: 48135

[usurped from Yamaha manual #LSI 222030]

To digitally produce the sounds created by a piano, violin, or flute, the number of operations which must be performed requires uninterrupted micro-processor operation. However, using the OPN FM system, it is possible to create rich musical sounds.

The FM system can also be used as a synthesizer to produce a wide range of sounds. OPN functions are compatible with the YM2149 (SSG) and AY3-8910. Although these devices can only generate square waves, they are in widespread use due to simplicity of control; systems which use them can be enhanced by replacing them with the OPN chips.

The OPN LSI is manufactured using Yamaha's Si-gate NMOS process, It includes two sound sources: the FM system and the SSG sound sources. Since these sound sources can each produce three musical sounds, a wide variety of synthesized tones can be produced.

Features
----
* FM system produces up to three different sounds at same time
* Each of the above three sounds allows sound effects and composite sine waves (CSM) to be created.
* Three square wave sounds and white noise for compatibility with SSG
* Two 8-bit general purpose I/O ports
* Wide range of operating frequencies available with internal clock divider

[Adds 108 additional control registers to the Yamaha YM2149 core. The registers control 2 timers, ADSR envelope w/ 96 dB range, dividers, feedback, etc. Output of OPN is sent serially to a 16-bit D/A converter, YM3014]

Principal Functions
----
a) FM sound generator w/ three modes:

I) Music - four operator cells allow FM sound source to produce
three sounds simultaneously. Eight operator cells
combinations are possible.
II) Effects - frequency parameters of four operator cells can be changed
so that one of three sounds produce a sound effect while
the other two are use as in the music mode.
III) Voice - one of the three sounds used in the composite sine wave
mode. Can be used simultaneously with two other sounds
in music mode.

[Configuration tables are given for brass, string, piano, flute, oboe, etc.
Production of chorus and tremolo effects also possible.]

b) SSG - Apart from FM generator, this section functions as YM2149 chip, so a total of six sounds can be produced

c) Two timers are provided and can be used as reference signals for key switch scanning and tempo clocking.

WRONG! WRONG! WRONG!

Only our very old DC Formatter prior to version 3.0x had this problem (and
still do, since they obviously still exist on someone's system somewhere).
We basically cut our teeth on that program.

Many DC Utilties my ass! I can gurantee we know a lot more about the operation
of TOS and GEM than 99% of the folx (including you) out there.

If you have hard evidence, I will recend my statement. Until then, it is slop!

>the buslines available on the VME/Atari (TT/mega)bus slots? Like for instance
>a 68040 board that takes over the machine and delegates the on
>board cpu as an I/O handler ... ?

No, it's not, because the things that can go on the VME bus in the TT can't be bus masters. The TT's VME bus is slave-only, meaning the motherboard can instigate an access to the VME board, but not the other way around. It is not unreasonable to suppose that future Atari machines may have full-blown VME where the VME boards can be bus masters, and then you could do this.

>Dave Small has already shown that it's possible
>for the ST...:)

No, he shows that it's possible to wire a 68030 into the ST. I don't know how he tells the 68000 to go to sleep; maybe you have to cut the whole thing loose, maybe you just have to cut a few traces (like power and ground :-) to get it out of the circuit.

I am searching a surses package (in C source code format) for the
Atari ST. It would be great if this package can handle termcaps but i can live
without this.

Please don't post a follow-up because i don't read all of theses
news-groups so e-mail me!

2402. Mega2 to Mega4 upgrade?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-20 20:49:38 UTC
From: freds@hpspdra.spd.HP.COM
Message-ID: <24150001@hpspdra.spd.HP.COM>
Source record: 48048

I have a MEGA 2, would like to add more RAM to 4 meg.

Can I just solder the new memory chips in place? Do I have
to do anything else?

I have a good ESD safe workarea and a great vacuum desoldering
tool. So solder removal is not a problem.

I have the latest Rainbow TOS installed. I put it in last month.

thx

freds@hpspdra.hp.com

2403. Re: Mounting ST in another case

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-20 21:11:30 UTC

Message-ID: <1991May20.211130.19023@chinet.chi.il.us>
Source record: 48139

A company in St Charles Illinois, Compu-Seller West (used to be Computer Cellar), has made a nice little business of rack-mounting ST-s for studio use. Their prices and service tend to be somewhere to the good side of excellent, so if anyone needs one of these beasts, it's probably worth calling them. Sorry: I don't have the number handy.

Can you describe what you want to do? I know that I mixed it up in the
last post (first in the chain/first installed)! To make it good I have
included some, that does what you say you want, but what good is it, can
you give an example?
The routine I have included will every it is called check if it is the
first routine on that vector chain. If it is not it will unlink it self,
insert itself in the start of the chain, and then call the remaining routines
in the chain.
One funny thing is to install two of these, they really fight to get the first
'seat'.
The code will only work if all routines uses the XBRA protocol.
It is written using the shareware assembler, TurboAss, available at
atari.archive.

Source record: 48070

Is there a nice way to tell TOS (version 1.4 and higher) *not* to
cache a drive? I want to share a drive over a network; clients
will see the drive as read-only, but I'd like the server to be able to
write to the drive. The only problem is that if the clients are caching
FAT and directory info, there could be problems when/if this gets
changed. Has anyone ran into this problem before? If so, what did you
do about it?

Your fixes were also fixed in the AutoSwitch-driver.

>How do you tell accs and the AES about the new screen size, I know that you
>have a reputation for making some really awsome hooks into TOS/GEM.

I never said, that the AutoSwitch-feature is 'clean'. Yes, i have to change
some internal AES/VDI-variables. I am not very happy about having to do such
hacks, i personnaly prefer to programm conforming to the rules. But when i
did the autoswitch feature, i knew _what_ i was doing.
Look at Chameleon, this DA does things that are not 'normal' for DAs. But
it supports XBRA, hooks in the traps (I know, DA are not allowed to steal
trap vectors!) and so on. BUT this tiny thing works on _all_ TOS versions,
with _all_ 680xx processors and it does not crash on resolution changes. It
simply works. And you must know that i develloped it when there was no TT
or even 68020/30er boards.
If i do a next release of Chameleon, it will be an auto-folder programm
for the Traps and a CPX for configuration. The new SM124-emulator for
the TT-High mode is done in this way.

My reputation in germany is very good, i am often asked how to do something
in legal ways. I beta-test lots of software to see if everything is
according to the rules.

> But you can't tell accs that the screen size have changed - can you?

If an DA uses form_center, wind_get or some of the other AES functions that
have something to do with screen-resolutions, the DA gets the right values.

>But not everybody can! If I send my version to atari.archive, (driver bin
>and source only) would you care? Should I release it as a Patch like KAOS,
>so that everybody that allready have overscan can patch it?? (sick)

Since you already send it to atari.archive, i have nothing against it ;-)

I must have been unclear at some point. Imagine a file selector
replacement program for the AUTO folder. It must hook into TRAP #2,
and its trap handler must become active _before_ the ROM AES.
So this program must reside somewhere at the beginning of the XBRA
chain, not at the end.

I am very sorry, I will go somewhere where I can not harm people, sorry.

I would only help _the_other_ people, not flame anyone!
I kind of cry when I see a great pice of software like the Calender, or great Idea like SFX and DC-desktop and it then don't work!

The Idea I had was that if I could show what people did wrong, other people did not have to do the errors.
- and ultimately I could get more good programs!

I was wrong, people don't care about quality. Many people blame TOS for many bugs. I have heard people claim that there is a bug in the AES that means that it can drop the menus while the VDI is drawing (also long time programmers that would claim that they was among the best 1% of programmers).
And who blames them, there are so many programs that do just that. (also Commercial)
And who belive you when you tell them that it is a bug in the programs, and not in the operating system. (some even suggest that the programs that work correctly, uses some kind of workaround!)

I had a list of topics. On top of the list was the use of 'wind_update()'.

Mark Tilden, in the Hardware Lab (mwtilden@watmath.waterloo.edu) has done
something like this. He put the CPU in a tower case and devoured the
1040 case to turn it into a detachable keyboard by cutting off the stuff
at the back.

Yes, he put all power supplies, the floppy drive, everything, in the main
box. He also added a battery for the clock.

I am upgrading to a PC, so I no longer need the following stuff

ATARI 520ST original computer, with no internal drive
TOS in ROMS. Also available is TOS on diskette. Includes
external single sided drive. Works perfectly. Includes
basic software to get you started, like word processor, terminal
program and stuff.

Price: Please Make Offer

ATARI SC1224 Color Monitor. Has perfect picture and in very good
condition. No sound.

Price: Please Make Offer

Also available is a power supply for an ATARI external disk drive

All items WILL be sold.

Thanks

Saurabh

2417. Re: Using Mac fonts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-21 22:47:51 UTC
From: Bob_BobR_Retelle@cup.portal.com
Message-ID: <42569@cup.portal.com>
Source record: 48062
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Todd Drga asked about using Mac fonts on an ST...

It's entirely possible to convert Mac fonts to use in GDOS applications, but it's not a trivial task, nor is it particularly easy to do.

The program I've used is FONTZ, a commercial product of Neocept, Inc. It will convert several different types of fonts into GDOS compatible fonts, includin Mac and Amiga. It works well, and allows you to touch up the converted fonts and even design your own original fonts.

The sticky part is getting the fonts into the ST in the first place.

My solutions involved using not only the ST, but a Magic Sac Mac emulator and pc-ditto, the IBM emulator.

Most Mac fonts are available in various point sizes. However, they are usually appended to one another in one large font file. FONTZ will only process the FIRST complete font set in such a group, and ignore the others. Usually this will be the tiniest point size, making it very difficult to scale the font to larger, more usable sizes.

The solution is to go into Mac emulation mode and use the FONT/DA MOVER to split up the font and save it as individual files, one for each different size of the font.

This will also take care of the problem of unarchiving the fonts, as you can run STUFFIT to unstuff or unpack the font in Mac mode.

Then you're faced with getting the font onto an ST readable disk. This can be accomplished by using the TRANSVERTER program to convert the files onto ST disks.

If you don't have a Mac emulator, your options are very limited. Most Mac fonts are either STUFFed or PAKed. Unfortunately, as far as I know there is only an UNPIT program for the ST, no unSTUFFers. If the file you want to try converting is STUFFed, you can run the IBM emulator, pc-ditto, and use a PC utility that will unSTUFF the files onto ST readable disks directly.

Again, FONTZ will only convert the first font, if there are more than one font sizes in the file.

Another solution would be to have a Mac owning friend split the fonts up and modem the files to you.

And lastly, most Mac fonts are Shareware, not Public Domain.

It's a lot of work, but it can be worth it..!

BobR

2418. 68881 for the Atari 1040

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-22 07:52:24 UTC
From: keiths@cadence.com
Message-ID: <1991May22.075224.13978@cadence.com>
Source record: 48057

Hi,

I wonder if anyone can help. I am trying to hook up a
68881 coprocessor to my 1040, to use with the Laser C floating point
library (lib881). I have been following the datasheet instructions
for the 68881 but am unsure whether I ve the addressing right. As
I understand it, the Laser C library looks for the 68881 control
register at address fffffa40 (found this by disassebling the code)
so I have created address decode logic to drive CS true at this address.
But what needs to be done with FC0-2? I am assuming that the 68881 is
addressed in supervisor data space, but is this true?

Anyone who may have done this, please email me or reply to the
net, I'd appreciate some help.

Keith.

Good plan! After I did it I couldn't believe I had waited so long.

>Can I just solder the new memory chips in place? Do I have
>to do anything else?

First you have to make sure that your motherboard does indeed have the holes in the circuit board for the extra memory (apparently about 10% of the boards do not). If so, you're all set. Atari filled all of the holes with solder (either out of malice or just lazy wave-soldering), so you'll have to suck the solder out of 300+ holes before you can do anything else. That's what took me the most time.

Basically, all you NEED are 16 RAM chips and three 33 ohm resitors. It's not a bad idea to use sockets for the chips, and 16 .1 uF capacitors as well. There are holes in the circuit board for the capacitors and resistors.

>I have a good ESD safe workarea and a great vacuum desoldering
>tool. So solder removal is not a problem.

Good! You'll have an easier time of it than I did.

For those of you that don't have an ESD safe work area, you might check out the sidebar article in April's Atari Informer... I used these tips when I did my work.

I performed this operation last month with great results. I ordered the parts from D&P Computer (800-535-4290), and they sent me a printout of a GEnie file that had instructions. They also sent along an Atari User magazine... nice guys.

The GEnie instructions had good tips for avoiding ESD, cleaning off the flux, and periodic sanity checks. If someone has GEnie access, I hope you'll post these to the archives.

Good luck!

Hello.

I locking for 19-pin D-sub connectors (Female to solder on PCB and male to put on som cables (with caps)) I can't find it some there. If you now there i can bye it please tell me! I am also locking for cheep 4 MB simms.

2423. Re: using GDB

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-22 16:44:43 UTC
From: ZVD007@DMSWWU1C.BITNET
Message-ID: <91142.182214ZVD007@DMSWWU1C.BITNET>
Source record: 48058

First of all I want to thank all who replied.

I was told that I have to use the -gg option to get debugging info and then
have to use sym-ld.
But there is a big problem: when I enter gdb and try to read in the sym-file
I get two bombs; searching for a solution, I found, that gdb supports no
longer the -gg option, one has to use the -g option. So, I tried that, and
gdb doesnt crash, it can set breakpoints and list the source, but when I
run the program, it allways receives a signal null and when I try to cont
the I get two bombs, but the debugger doesnt crash, the program is just halted.
Is there anyone with a solution of this problem?

Thanks in advance
U.Kuehn

2424. Re: TT VME Bus, and extending it

> for the ST...:)

Nope, it isn't possible, at least at the moment. The main reason is
that the TT's VME bus is only D(ata)16(bits), A(ddress)24 (one vme
connector), which is fine for a Mega STE, but you need D32, A32 to
really handle an 030. I'm also not completely clear whether VME
supports Bus mastering properly, we have the spec here, but I was only
interested in the electrical characteristics when we were putting our
DSPs on the VME backplane.

This does bring up a pet idea of mine however. I wonder if it would
be difficult to implement the electrical part (buffering etc.) of the
missing VME connector. So that one could connect a TT to an external
VME Backplane in some nonstandard way and have a true D32, A32 VME
card cage for it. Comments anyone?

> do this.

Umm. I think you err in some ways. There is no rule that says that
a peripheral card in any system, bus master or otherwise could not be a cpu
card etc. What you are saying is simply that the VME card in a Mega ST or
TT030 cannot access the ST's native memory DIRECTLY. It is quite possible
therefore to at bootup, transfer TOS into some 030 memory mapped at the
correct address on the VME card from the 68K side, and implement a
communication protocol with the 68000 as BUS master with the 030 card.
Screen accesses are emulated by trapping the access and emulating the
function (tell the ST you have data and where it is ... it will then
do the screen draws _IN PARALLEL_ with the 030 on the co-pro card.)
In addition programs which use library calls can have the library functions
themselves queued for the 68K and while this does'nt speed up redraws
it sure does offload the 68030 of such tedious work. IE the communications
can be handled at several differnt levels (The easiest being the passing
of LineA exceptions to the 68K)

I have done several designs (DSP co-processors) for PC's based on this
principle and in fact this works BETTER than bus mastering because you
can do two things at the same time.

All this requires is one interrupt from the VME card to the ST and
a region of shared memory (I think 4MB is sufficient)

Does anyone happen to have any code on sensing if there's a GEM window on the screen from within a stay-resident (auto folder) type program. Maybe there's a C function?

From: ralph@prosun.first.gmd.de
Message-ID: <677@bigfoot.first.gmd.de>
Source record: 48059

Hi,
I'm searching for stereo D/A transformer for Mega ST
computer with up to 16 bit width. Who knows anything
about buyable hardware with or without software.
Who has any experience on connecting a serial digital
output (must be built) of the ST to a D/A transformer of
an amplifier!!
Is it possible to use this setup as a cheap output
variante? So I need only the analog/digital transformer.

Is there anybody experienced with ideas like these?

Thanks in front. Ralph

You could do this from a DA by calling wind_get(WF_TOP...). If there is
a GEM window, there must be a top window. If there is none, you won't
get a top window handle other than 0 (desktop window).

2429. Vsync, sprites, Aline

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-23 12:03:42 UTC
From: D.M.Johnson@newcastle.ac.uk
Message-ID: <1991May23.120342.3876@newcastle.ac.uk>
Source record: 48071

I was messing around with the aline routines in the 'COMPUTE! volume 3 - DOS' and can across this problem:

I was ploting sprite to the screen (using either the Blitbit or Sprite routine, I can not a present remember which) in assembler. I was waiting until the VVsync to prevent flicker: no problem here. the sprite moved around the screen. flickering slightly (this was do with the code - I fixed it so there was no flicker) but when the sprite moved around the screen. There was a region in which the sprite disappeared as it moved through it, (it got worse when I removed the wait for the Vsync).

Could anyone explain what is happening and if so whats the cause and the cure.

Machine used

2.5meg STFM
mono Monitor
1.2 OS

Dave

P.S. If the above does make sense I will try and dig up the program and post it so some one could help me.

No one is asking you to leave, but if you are going to make claims about software that doesn't work (especially when the company that makes the software is on the net AND when you have never complained OR registered that company's software directly with the company), then you had better substantiate your post!

You are once AGAIN making an unsubstatiated claim about our software!

DC Desktop DOES work, and we have _many_ satisfied customers! DC Desktop, however, is _highly_ ROM specific in order to wedge in and supplement the OS functions. If you have problems running our software, I would ask you two questions:

1) Why not contact us directly, instead of spreading unsupportable claims?

2) Have you contacted our Netherland distributor, who has a specific version for the ROMs you probably have?

There is also a section of lower memory used by the AES which tracks
windows and their various attributes (including whether or not they are
open).

This area, however, is not documented, is very ROM dependent, and would
be called an _illegal_ method of determining such by Atari Corp.

If you are a hacker, you might want to mess with this, otherwise, a TSR
can never find out the answer to such a question.... Although, one might
install a TRAP #2 wedge, and perform a wind_get call at some safe time.

Don't write me asking for more info! I will ignore any request for further
details. I've probably said more than my friends at Atari would like...

Source record: 48074

In drawing programs, it's common to allow lines between the mouse cursor and a fixed point. Another example is the rubber-band boxes for selecting a screen area. Would some kind soul tell me how they're done?

It's easy enough to determine the start point by using the EventMulti loop to detect the mouse button's first click, but how does one keep track of the mouse cursor and draw to it AND know when the mouse button is clicked again?

Is it necessary to drop out of the EventMulti loop and use lower-level facilities?

george@m2xenix.psg.com

I second this plea for help (actually my fourth). Regarding the -gg
option, I received the following from Jwahar Bammi:

>compile your program with -gg -D__NO_INLINE__ and it should hopefully work
>gdb is very much out of date. gnu has dropped support for -gg format,
>and the latest versions of the assembler dont support the additional
>info produced by -gg. one day i'll get around to doing gdb properly.

Defining __NO_INLINE__ gets rid of the two bombs, but I also get the
null signal. You are supposed to be able to tell gdb to ignore the
null signal, but when I try to do this, gdb tells me that 0 (the null
is signal number 0) is not a valid signal number. So, I can't change
anything. I have about given up on gdb, and have reverted to using
Gdb (the Gallivan debugger--lots of print statements!).

Yes I follow you now, I thought that the AES was as nice as the VDI. But it
isn't - it eats all AES function calls (it don't link to the next in the
Gem-vector-chain...).
It replaces the trap #2 vector at least 2 times, this surpriced me, and
the program that I tried to install.
I tried to install a trap#2 routine that would install a AES handler when the
AES had initilized itself. The first solution to this problem I thought about
was to monitor the trap#2 vector for a non-XBRA routine, but AES unlinked
the routines (I had a number of clones, that could be hooked in the vector,
and shoot (w. RTS) if they failed).
Then I thought that a OpenScreenWorkstation would tell when the AES was init.
but a quick check showed that auto-folder programs also can open and close
workstations, too - soo :-(
Things would be much more easy if there was an exec_aes ;-) or a bit-vector
where one could tell which part of the OS that had been init.'ed.
(AND a bit-vector called >in_TOS< so that one could use Tos semi-reenterent)

At this point I began to doubt that it could be done (legally)... So I
tried to look at formdoit, but that did not help. Then I looked through all
my docs, AES (see about), VDI (can't be used), Gemdos (likevise), Xbios (do),
Bios - now here were something - setexc(), did AES enable it's own trap
handler with this?
A small program showed that it didn't, but there were something else, yes
it enabled the evnt_critic vector with it!!! - heureka!

Now - is it legal to assume that it will always be this way? Allan P.?
Ken B.? - is it?
You have not been very help-full on this subject, so I include a small program
that uses the principe. Please flame this Allan and Ken, then tell how we
are supposed to do it!!

The program Form_Pop makes the dialogs pop-up under the pointer, real usefull
for Julians R.'s BigScreen...

Comments please!

From: micro@imada.ou.dk
Message-ID: <1991May23.170948.12410@imada.ou.dk>
Source record: 47995

I just want to continue my list of bad programming pratice, but without examples.

- Don't use ScanCodes to check for any key on the main keyboard, use them only to check for HELP, UNDO, Fx, ESC ...
Don't use it for 'Z', 'Y', '[', or any other. If you use ALT+key, then use the KeyBoardTable to convert the scancode to ASCII, then check that.
Don't replace the buildin Keyboardtable ('cept if that is what your program is supposed to do).

- Remember to use wind_update(BEG_UPDATE)/wind_update(END_UNDATE), when you are drawing on the screen. To avoid an other process smears the screen (eg ScreenMgr)

- Don't assume that because you only have one window, that you then don't have to process WM_REDRAW or VM_TOP/WM_NEWTOP messages.

- When you Allocate memory, then remember to leave some (8Kb+) for AES, VDI, GEMDOS, and accessorys. On a related subject, don't :
p = Malloc((long) int_var);
This will work if int_var is less than 32Kb, else it will fail big!
The strange thing is that if replace it with a 'malloc-stdio' then it will probaly work, because it often is suppost to take int vars.

- Don't mix BIOS/GEMDOS screen output (input?) with a Gem program. There might come graphics cards that jump into textmode when it is told to output text like (PC's).

- Stop using the LineA routines. (I need help on this - also Init?).

-Klaus, micro@imada.ou.dk

Data space, but it need not be supervisor. We did this so programs and
libraries could use it without becoming supervisor.

2439. 68020 conversion board - update

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-24 00:33:36 UTC
From: ekrimen@ecst.csuchico.edu
Message-ID: <1991May24.003336.17510@ecst.csuchico.edu>
Source record: 48073

A couple of weeks ago, I mentioned a board that would convert a 68020 chip
to a 68000 pin-out. Someone was selling this jewel on misc.forsale.computers.
Well, he sold it that night. In any case, here's the original message,
including the address of the manufacturer of the board. I haven't called
yet -- too much stuff to do. I will do it sometime. If you do indeed
decide to call, please post whatever information you gather.

Article 11265 (6 more) in misc.forsale.computers:
From: jimwh@wipe.tv.tek.com (Jim Whittlesey)
Subject: 68000 to 68020 board
Message-ID: <1991May8.232511.658@tvnews.tv.tek.com>
Date: 8 May 91 23:25:11 GMT
Sender: news@tvnews.tv.tek.com (news user)
Distribution: usa
Organization: Television Systems Division, Tektronix, Inc., Beaverton, OR
Lines: 19
Originator: jimwh@wipe

I have this little board that converts (plugs into a 68000 scoket)
a 68000 to a 68020 with FPU (68881). The board has three PALs,
a 12 MHz 68020 and 16 MHz 68881. All parts are socketed.
The board is made by:
Computer System Associates
7562 Trade Street
San Diego, CA 92121
(619) 566-3911

I have NO documentation. This board is sold AS IS.
I have no idea if it works.

Asking $40 or best offer. Buyer pays shipping.
for another $40 I'll through in a spare set of
CPU (68020 16 mHz) & FPU (68881 16 mHz).

Jim Whittlesey (503) 245-7139 home PST
jimwh@videovax.TV.TEK.COM
End of article 11265 (of 11270)--what next? [npq]

It sounds like a real bargain, and I'm sorry I didn't jump it. :^(

>When the sprite moved around the screen, there was a region in
>which the sprite disappeared as it moved through it, (it got worse when I
>removed the wait for the Vsync).

>mono Monitor

The trouble is, you are drawing of the screen as it is being displayed.

Possible solutions:
1. Write faster wipe/draw procedures
2. Use double buffering
3. Write a wipe/draw that interlaces wipes with redraws

Also, try move the Vsync() around. Try Vsync()ing after you erase, but
before you redraw.

>a screen area. Would some kind soul tell me how they're done?

The AES call graf_rubberbox() is one way.

>It's easy enough to determine the start point by using the EventMulti
>loop to detect the mouse button's first click, but how does one keep
>track of the mouse cursor and draw to it AND know when the mouse button
>is clicked again?

>Is it necessary to drop out of the EventMulti loop and use lower-level
>facilities?

It doesn't make much sense to stay in the EventMulti loop, since nothing
should really happen until the rubberbox is finished. eg. What should
happen if the box extends over a desk accessory's window? Does it get
an event?

I use graf_rubberbox() normally, but I guess you'd use VDI calls with the
AES VDI handle if you wanted something like a rubber line.

Mine is a Goldstar. It took one adjustment to make it work at all Hz's, and
the adjustment did not affect the performance in "regular" 60Hz mode. It is
a bit difficult to do this adjustment while the monitor is off, so I would
recommend using the tool designed for this (a plastic TV screwdriver).

Fontkit Plus V3 will convert Mac fonts to GEM fonts (though I haven't tried it). Fontkit Plus is a great package for editing bit-map fonts. I've used it for creating screen fonts for use with Fleet Street Publisher 3. It will also convert Calamus fonts.

It's available from the ST Club in England. Cost is about 19.95 pounds. If you want the address, e-mail me and I'll find it.

Nick Coyne European Space Agency, Darmstadt Germany.

Hi
I am trying to find out wether there is available anywhere in the PD a
programm to help me with the design(layout etc)of printed circuit boards.
Is there one that will give me a circuit board design from a circuit diagram.
If there is one can I get it from an Ftp site somewhere.
If no one knows of one available in the ftp then is there one comercialy availa
ble ?.

Any help or pointers in the general direction will be greatly received.
Also if some one out there has got and has used something like described above
is it any good?.

|>
|> Jon

Your local dealer shut have the original Atari ROM's. They are aviable in 2 and 6 chip version. The MEGA ST2 has TOS normaly in two ROM's. If you want to use the version with 6 ROM's you must change the setting of some soldered jumpers on the motherboard :-(.

2449. VME bus on the TT

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-24 14:06:20 UTC
From: vspicer@ccu.umanitoba.ca
Message-ID: <1991May24.140620.16320@ccu.umanitoba.ca>
Source record: 48082

Hello world
I'm trying to interface a home-made data acquisition board designed
for an ST into a TT. I've made an adapter board which maps the VME pinouts
to their ST expansion bus equivalents so the existing board just plugs in.
The problem is that when I attempt to access the VME mapped memory area
(FE000000 base address) I get a bus error, 2 bombs. A logic analyser reveals
the AS* line on the VME bus isn't being set. I'm presuming that when I try
to access VME memory space:
1- The address in question appears on the VME address lines.
2- AS* changes to low to indicate the address is valid.
3- An identity comparitor on my board sees that *AS, compares
the address against a set bit pattern and engages the rest
of the board if they match.
The board DOES work on our ST machine, so the board isn't at fault. Shouldn't
AS* change state when addressing VME memory space? Or is there more to it
than that?

thanks in advance
vic spicer
.

2450. Re: Using Mac fonts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-24 14:43:08 UTC
From: wilsona@dcs.glasgow.ac.uk

Source record: 48089
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

The easiest way to get stuff from a Nac is to format a DOS disc on an FDHD equipped mac (all of the later ones), and simply copy the fonts onto it. Stick the disc in an atari and run 'mac2gem' from (wait for it...) the ST Club on it. Easy. No problem. If you do not have access to a Mac then it is a problem. There is some PD stuff on terminator. A non FDHD Mac involves connecting the computers together. Note: Format the MS-DOS disc using 'Apple File Exchange'.

Alan Wilson (No relation to anybody connected with the ST Club...)

2451. Display List Interrupt on an ST?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-24 17:53:23 UTC
From: erik@mcrware.UUCP
Message-ID: <6640@mcrware.UUCP>
Source record: 48086

Is there a way to make some number of consecutive scan lines, all point to the same memory (i.e. scan lines 0-10 all point to the same 160 bytes of display data). Can you simply change the screen pointer on the fly (memloc 0x44e I believe)? If this is possible, how do you set up the interrupts on each scan line?

Any clues will be graciously accepted.

Erik R Johnson erik@mcrware.com

uace0@menudo.uh.edu (Michael B. Vederman) writes:
>No one is asking you to leave, but if you are going to make claims about
>software that doesn't work (especially when the company that makes the
>software is on the net AND when you have never complained OR registered
>that company's software directly with the company), then you had better
>substantiate your post!

Now you wait a second, the software is shareware (or it might have been
a demoversion). It is therefor my right to try the software first and if
it don't work - then erase it from my harddisc, right?
You can't expect that I pay for software I can't use, can you? If you can
then I have some ideas to make big money!
Whats more, you can't expect that anyone with TOS 1.4 or the least programming
skill will pay money for a formatter!

>You are once AGAIN making an unsubstatiated claim about our software!

again, correct me if it is wrong, I tried a formatter of yours, I could not
use it, now why should I try any other of your products?
Ok, I did try another(dcdesktop), and it did not work (not everybody have
an english desktop - and as you probaly can see english is not my main
language, so there might have been a slight chance that that was the case,
right?).

>DC Desktop DOES work, and we have _many_ satisfied customers! DC Desktop,
I think it depends on who you are!
I would not be satisfied with software that took chances with undocumented
variables/text/functions.
And I hope for all the people that have bought your software that _you_
stay with Atari for many TOSses.

>however, is _highly_ ROM specific in order to wedge in and supplement the
>OS functions.

Yes that is the problem when you have spent to many hours with a disassembler
in the area about 0xE0_0000. One can not resist the temptation - right?

> If you have problems running our software.
>1) Why not contact us directly, instead of spreading unsupportable claims?

I did not contact you because when I needed a formatter (PC-comp.) I tryed
out many diffrend ones (yours included), and If I should have mailed to all
the people with formatters that did not work, I would probaly still be mailing
today. And I did find a better alternative (FreeWare with source).

As I said in my previous post, it was not my intension to flame anybody, but
rather to give an example that people could relate to, and I thought that

people knew your software - right...

This is becomming annoying, I wanted to help newcommers writing better software and I end up arguing with a long time hacker.

>
> Questions:
> What does it generate?

Bitmaps in any of several formats, depending on the printer driver.

Calamus uses a proprietary font-scaling technology (actually, I think it's licensed from Agfa Compugraphic) and generates its own bit images for both screen and printer output. Because its font technology is both very good and very fast, you get a high degree of correspondence between what you see and what you get, and you get it quickly with a bit-image printer such as the Atari SLM804 or SLM605.

> Are there any public domain to-postscript-converters available?

None that I am aware of.

If the only printer you have available is PostScript, then Calamus is not the right tool. PageStream is probably what you need.

PageStream 1.8 has its own font-scaling technology that is markedly inferior to that of Calamus, but it also has PostScript output drivers for monochrome and color printers that call upon the PostScript interpreter to supply fonts when possible. That means PageStream is slower than Calamus and has less correspondence between the screen image and the output image, but it also means you can get excellent type quality and, or course, portability.

PageStream 2 is supposed to be able to use PostScript fonts to generate its screen images, but I don't know whether it is available yet.

Yes, ofcause there is! All programs have vars that keep track of what they
are doing!

>This area, however, is not documented, is very ROM dependent, and would
>be called an _illegal_ method of determining such by Atari Corp.

If Atari ever told where these things were and the meaning of the variables,
It would probaly mean that Atari not intended to upgrade GEM/TOS anymore,
so lets hope, that it never becomes legal...

>If you are a hacker, you might want to mess with this, otherwise, a TSR
>can never find out the answer to such a question.... Although, one might

NO YOU WOULD NOT!! WE DON'T NEED MORE BAD SOFTWARE!!!
There is not enough hacker in you - a real hacker would not spend hours,
trying to figure out what a bit in os-private-area is doing. A real hacker
would monitor wind_close,wind_new,wind_open. (and tell everybody that it
don't work from the desktop).

>Don't write me asking for more info! I will ignore any request for further
>details. I've probably said more than my friends at Atari would like...

Real friends tell you when to stop!

-It is very bad pratice to use anything, that make Atari look bad when they
release something good (new Tos,Gdos,filing system,...).

Since you have to write a little device driver, you also have to take care
of the media change state. If you return 2 all the time at Mediach() calls,
TOS should not keep old information it it's caches.

BTW: Do you address the drive on file or on block level? If you write some-
thing that intercepts the trap #1 vector, you don't have to do anything
like this, since *you*'ll get all calls first...

The same thing happens to gfa basic sprites. The only solution I
see is to try using two virtual screens...

Pardon me if I'm wrong, but everything I've ever read about the ST's
GEM (specifically the Abacus volume) has said "V_OPNWK AND V_CLSWK ARE
NOT IMPLEMENTED IN ATARI ST GEM" (OK, maybe they didn't use all caps
:-) Isn't this a really bad idea, especially when you've just flamed
someone for using undocumented variables in another posting?

Or does GEM use these these functions itself upon starting up?

This came from a File that I found some time back on Genie, it could
be of help to otheres, with the Trap #2 problems.

Category 2, Topic 19

Message 108 Sun Nov 13, 1988

C.F.JOHNSON at 16:19 PST

Steve,

Stealing trap #2 is not quite as easy as Dan made it seem; you can use
his method (except for the "magic cookie"...more on that later) with all
the other trap vectors (1, 13, and 14), but intercepting trap #2 is
uniquely difficult because the operating system keeps replacing its own
address in the vector! TOS seems to reset $88 (trap #2) every time
you runa .TOS or .TTP program, or show a file from the desktop.
(And maybe at other times too...)

After lots of thrashing around for methods to solve this thorny
problem, Bob Breum (Easel ST), Wayne Buckholdt (Turbo ST),
John Eidsvoog (fellow CodeHead),

and I came up with a method of intercepting trap #2 "safely"...in
other words,

so that the system can't de-install you while you aren't looking, and
so that other programs which use the same method can coexist peacefully.

The method is not exactly obvious....and that's why there are a lot of

programs (e.g. FSEL60) which don't get along with other programs that
need to steal trap #2.
Some programmers, in order to keep their software working,

resorted to desperate measures...like checking the trap #2 vector every

vertical blank interrupt and just replacing their address if it ever
changed.

This method does work, as long as your program is the only one that steals

trap #2 --- which is a ridiculous assumption to make, with more trap #2

thieving programs appearing every day.

We decided (all of the folks listed above) to publicize thisinformation as
widely as possible, in the hope that everybody's "GEM fixer-upper" programs
will be able to get along.
The following section of assembly code illustrates the process,
with lots of comments:

```
*********************************
* *
* Intercept the trap #2 vector *
* *
* Code by Charles F. Johnson *
* *
*********************************

* Last revision: 06/26/88 12:13:32

* In order to steal trap #2 permanently, it's necessary to watch for a

* certain BIOS call from the operating system - a setexec() call for the

* critical error vector. TOS issues this call after running a .TOS/.TTP

* program, and immediately after changing the trap #2 vector at $88. So

* when this call comes through, you know it's time to re-steal trap #2.

* Good luck, Jim. We're all counting on you.

move.l retsav,-(sp) ; And return to the caller

rts

retsav:

dc.l 0

not_auto:

dc.b '[3][ Test alert box | ][ Install |Cancel]',0
```

(Whew! This is turning out to be a lengthy message!)
Anyway, one really important point to remember when you
steal _any_ of the ST's trap vectors -- once you steal it,
NEVER reset it to what it was when you grabbed it.

To disable yourself, use a flag and jump past your code, or some other
method...if you actually replace the vector itself, you'll be cutting
out any other programs that have installed themselves in the chain.

Stealing an ST vector is like grabbing a tiger by the tail - once
you've got it, you'd better not let go!

(Note that the operating system itself is guilty of this crime.BIG sigh.)

Now on to the "magic cookie" method Dan proposed...in a word, DON'T!

We just went through a real headache trying to make MultiDesk compatible
with Atari's Diablo emulator for their laser printer.
The reason? The Diablo program used a "magic cookie."
The Diablo emulator comes in two parts, a program that runs in the
AUTO folder and an accessory that is used to set up the emulator.

The accessory looks for a certain magic number right before thetrap #13
vector, in order to tell whether the AUTO program is installed or not.
Works fine, again, as long as no one else steals the trap #13 vector
between the accessory and the AUTO program. The trouble is, a LOT of programs
and accessories (including MultiDesk) steal trap #13.
Result? A big mess.

A better method than the magic hockey puck is to issue an OS call with an
undefined function number, like BIOS #73, or AES #1200, and have your program

return a pre-defined value somehow, indicating that it's installed.
For example, this is the method that G+PLUS uses to let other programs
know that it's installed.
The program does a trap #2 call with $472B in register D1.

If G+PLUS is present, it returns from the call after setting D1 to the address
of its "backdoor" structure....so if D1 is unchanged after the trap, G+PLUS
isn't there.

Well, that's enough technical talk for one message.
Feel free to ask if you have any questions about the source code I
included above.

- Charles

Well I do hope that line noise did not corrupt this data, have only a
dumb upload option..

>>substantiate your post!
>
>Now you wait a second, the software is shareware (or it might have been
>a demoversion). It is therefor my right to try the software first and if
>it don't work - then erase it from my harddisc, right?

You are correct about DC Formatter, it is shareware. And as such, you have
every right to do whatever you deem necessary with it (including, but not
excluding FILE 13 - the trash).

If you were paying attention, I wasn't referring to that, but rather
DC Desktop.

Your original post (to paraphrase) said somethin like: "Many programs suffer
this problem, several come to mind including DC Stuff..."

Such a broad sweeping statement deserves attention and immediate rebuttal.

>You can't expect that I pay for software I can't use, can you? If you can
>then I have some ideas to make big money!
>Whats more, you can't expect that anyone with TOS 1.4 or the least programming
>skill will pay money for a formatter!
>
>>You are once AGAIN making an unsubstatiated claim about our software!
>
>again, correct me if it is wrong, I tried a formatter of yours, I could not
>use it, now why should I try any other of your products?

Again, you can act as you like, at least over here, it is a free country and
I respect your right to do what you want. HOWEVER (and this is a big HOWEVER)
you do not have the right to hurt someone else (or attempt to damage someone's
or some company's reputation) in doing so.

Your unsupported claims caused my zealous reaction.

I have already conceeded DC Formatter's problem with opening a bad VDI handle,
but this will not affect you (usually) unless you have GDOS installed. Barring
the use of GDOS (or equivalent), you should have been able to use it.

>Ok, I did try another(dcdesktop), and it did not work (not everybody have
>an english desktop - and as you probaly can see english is not my main

>language, so there might have been a slight chance that that was the case,
>right?).

Again, I already conceeded that point, so what's the point you are making?
DC Desktop is highly ROM dependent. We have and are working with our
overseas distributors to insure that it will work with non-American TOSes.
Which it does for all ROM versions we have been able to get our hands on.

>
>>DC Desktop DOES work, and we have _many_ satisfied customers! DC Desktop,
>I think it depends on who you are!
>I would not be satisfied with software that took chances with undocumented
>variables/text/functions.

You only have our guarantee that if you want these features in the manner
we provide them (supplementing the existing OS, not replacing it) then
this is the only way to do it.

Our knowledge of the workings of GEM and TOS is quite extensive.

The only "chance" the software takes is that it will not work on a version
it does not recognize.

>And I hope for all the people that have bought your software that _you_
>stay with Atari for many TOSses.
>
>>however, is _highly_ ROM specific in order to wedge in and supplement the
>>OS functions.

Double Click Software has been in business since 1986, and we have every
intention to continue developing and supporting the Atari computers as
long as they are around.

All of our staff have been using Atari computers since the days of the
Atari 400, and programming for just as long on them.

>
>Yes that is the problem when you have spent to many hours with a disassembler
>in the area about 0xE0_0000. One can not resist the temptation - right?
>
>> If you have problems running our software.
>>1) Why not contact us directly, instead of spreading unsupportable claims?
>
>I did not contact you because when I needed a formatter (PC-comp.) I tryed
>out many diffrend ones (yours included), and If I should have mailed to all
>the people with formatters that did not work, I would probaly still be mailing
>today. And I did find a better alternative (FreeWare with source).
>

Again, confusion in what we are discussing. I was talking about your claims
about DC Desktop. As for DC Formatter, do as you like...

>As I said in my previous post, it was not my intension to flame anybody, but
>rather to give an example that people could relate to, and I thought that

>people knew your software - right...
>

Sure, what damage can happen by just making a broad statement about software
that doesn't work and tacking on the end "and DC program have problems too"
(to paraphrase).

If you didn't mean to flame anyone, then don't mention names!

It seems quite clear from your posts that you singled us out of the thousands
of problem programs. Why? I can't begin to guess why. Perhaps your knowledge
of programs which have the problem you originally described (a bad VDI handle)
was not as extensive as you would have us believe, therefore, without providing
any real evidence, you committed a fallacy in logic and decided to group all
of our programs together, simply because a _very_ old program (our first)
exhibited the problem (the fallacy is 'generalization').

>This is becomming annoying, I wanted to help newcommers writing better software
>and I end up arguing with a long time hacker.
>
>Klaus, micro@imada.ou.dk
>
>>- mike vederman

If you want to help out, then don't attempt to come off as a 'know-it-all'.

State precisely what you have knowledge about and leave it at that.

Had you originally just said "I know DC Formatter has this problem. Others
may exist, but I can't comment about them since I don't have first hand
experience with them."

We would not be wasting band-width attempting to straighten out a misleading
satement.

And now back to the originally scheduled discussion...

- mike vederman

Source record: 48001

Klaus Pederson writes:
NO YOU WOULD NOT!! WE DON'T NEED MORE BAD SOFTWARE!!!
There is not enough hacker in you - a real hacker would not spend hours,
trying to figure out what a bit in os-private-area is doing. A real hacker
would monitor wind_close,wind_new,wind_open. (and tell everybody that it
don't work from the desktop).

Sometimes to get a very desirable prgram running, you have to break the
rules. Sometimes to get the features people want, you have to do whatever
it takes to get it done.

Then you just add the following to your documentation:

"This program uses several undocumented memory locations. These locations
are not documented and are subject to change in TOS revisions. We will
continue to support this product and make any changes required due to TOS
revisons resulting in the changing of these undocumented locations. We will
also provide updates due to such circumstances for free or at a minimal
shipping cost."

This is verbatim from our DC Desktop manual. We also list what trap vectors
we monitor and modify/use.

Our recently posted DC Topper also has a strong warning about its use of
undocumented TOS/GEM structures (including window resources and tracking).
Many, many people have been asking for a program like DC Topper (which
tops the window under the mouse automatically) since I've had access to the
net. I'd say the 'bad programming' was worth it. It was the fourth best
download on GEnie for April/May and has been widely praised by many...

Caveat emptor - Let the buyer beware.

We are very deliberate in letting people know that we break the rules in
order to give them the feature(s) they demanded.

It is an individuals choice whether they wish to benefit from such a
program. Otherwise, somethings would never be done.

I suggest that if anyone wishes to do research on stealing vectors, then they should save themselves A LOT of wasted time and get the document "The eleven commandments for taking vectors" (Or some such title) by Charles Johnson. Many many hours have been spent researching this subject, and PROVEN techniques and guidelines are given in this document.

Follow the rules outlined in the guide and you will have hours of vector stealing enjoyment! :-)

From: hvaalde@cs.vu.nl
Message-ID: <10058@star.cs.vu.nl>
Source record: 48003

micro@imada.ou.dk (Klaus Pedersen) writes:

>When I tried to make the code that installed the Trap#2 handler I found
>that it was possible to use the vdi from the auto-folder, a thing that
>I thought was impossible! The trick is to open a physical screen work-
>station. Simple and clean...

I thought it was common knowledge already, but it seems it isn't
I use the following way to set up vdi from the autofolder in a way that
the program can be run from the desktop to (use the program for over a year
no and the methode works on ST/STE and TT)

```
appl_init();
if (_GemParmBLk.global[0] == 0) /* that is check AES version number */
/* I am an auto prog */
v_opnwk( etc )
else
/* AES already initialized */
v_opnvwk( etc );
```

writing this without the source code beside me and with TurboC in
mind but it should look something like this.

The trick is that appl_init will not run if started from the auto folder
and thus the version number of AES will not be filled assuming initialized
global array this ends up as zero. So non-zero version number means AES
available thus workstation opened thus I should open virtual one, zero means
no AES so it is save to open real workstation.
Ofcourse under no circumstances the program may end without closing the
workstation since it is not done automaticly, since there can be only one
real workstation AES will bomb if the auto program doesn't close his properly.

If anyone is interested in some more VDI tricks give me a mail.

Hi -

Has anyone ever heard of an ST overheating and crashing or something when using the MIDI port? Here's my problem: I've had my 520STfm for about 2 years and only recently started using MIDI software. Two separate sequencers I have used crash occasionally for no aparent reason. The first software package I used was PD, so I thought it may have just been buggy. The software I'm using now (Mastertracks) seems to work fine, but if I leave the computer on running it for more than an hour or two, it crashes. After it crashes, I have to wait an hour or so before I can run the sequencer again. Other types of software seem to work fine (I leave UniTerm running almost constantly and it never crashes).

Any suggestions?

Confused,
Andy Dickinson

B.T.W. My synth is a Roland D-10, if that's a clue.

There is a port of g++ version 1.39 (and gcc 1.39 too) on ftp.thp.koeln.de, (134.95.64.1).

Calamus drives directly the printer, and it prints in graphics mode. So
I think it is impossible to use it with a postscipt printer. But if
you are looking for something with posttscript output, new PageStream might
be something. I have not even seen it, but I just read from it on
Atari ST User, so it is available in UK.

2470. Second HD mechanism

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-26 17:25:05 UTC
From: cscullio@ncratl.AtlantaGA.NCR.COM
Message-ID: <19111@ncratl.AtlantaGA.NCR.COM>
Source record: 48008

I've just added a second Seagate mechanism to my BMS 100 host adapter. The BMS software can format it and recognize it just fine, but I've been using Atari's HDX 3.01 to provide auto-booting (and formatting) of the original mechanism. HDX 3.01 doesn't want to recognize the second drive (partitions E: and F:). The BMS (Berkeley Microsystems) software does not provide an auto-boot feature, and I'd rather not go back to floppy-booting of the hard drive.

Any suggestions as to how I get HDX 3.01 to access the second mechanism?

> simms.

This 19-pin-connector, Atari used is indeed difficult to get. When
I moved my Mega-ST 'motherboard' into a tower-case using a
ready-to-assemble kit, I found, that 25-pin-connectors can be used
instead: just tear off 6 of the pins. The shielding on the 24-pin-
connectors fits easily over the distance-bolt (right term ? english
is not my first language :-)) that's on either side of the connector
soldered to the motherboard.

Hope, that helped you.

Greetings, PMH

This trick is 'not new', it is used by some boot selector programms (X_BOOT
and in some PD boot selectors...), you find example programs in the manual
of NVDI or even in some (german) ST magazines.

And it does not work with RAM-TOS versions, or even with the new STE or TT machines... (Please use the os_start entry in the _sysbase structure pointed to by the system variable $4f2.)

> A better method than the magic hockey puck is to issue an OS call with an
>undefined function number, like BIOS #73, or AES #1200, and have your program
>return a pre-defined value somehow, indicating that it's installed.

This method is not good. The 'unused' function call might be used in a future TOS version.
You simply have to install a Cookie interface for the TSR. The value of the cookie points to an internal TSR structure, so that a DA, CPX or PRG can configure the TSR.

Sincerly, Karsten (ki@opal.cs.tu-berlin.de)

2474. Re: How to use the VDI from the Autofolder

Newsgroup: comp.sys.atari.st.tech

Message-ID: <1991May27.001208.27105@imada.ou.dk>
Source record: 48022

Hi,
Roger send this code, but please don't use it, because:
o assumes that the ROM starts at $FC0000 (WRONG - might be $E00000 or
something else.)
o Don't use the XBRA protocol...
o Don't use the longframe system var...

Also it say that the Trap2 vector gets taken all the time, I have not
experinced that (but I am using tos1.4).
The code in the followup to Claus Brod question don't have these problems,
please try to put the program from the post in the auto-folder, and let me
know of problems.
And if you use the XBRA protocol you can unlink youself from any vector
chain (if all programs follow the protocol - and most do).
If you use the XBRA protocol you can see if you have been installed.
Please this is no flame, but a WARNING, don't use this code.

Roger.Sheppard@actrix.gen.nz (Roger Sheppard) writes:

>uniquely difficult because the operating system keeps replacing its own
>address in the vector! TOS seems to reset $88 (trap #2) every time

> (And maybe at other times too...)

I have never seen that problem, ones you have it installed, it stays there
just as Allan have tried to say here!!! (Overscan runs - don't it?)
The only problem is when to take the trap2 vector from the AUTO folder.

...
> * Trap #13 wedge routine

WHAT NO XBRA HEADER, PLEASE REMEMBER!!!

The HDX 3.01 does not support a second drive (lun 1), you would be
better in changing to a ICD host adapter and ICD software.

>>be of help to otheres, with the Trap #2 problems.
...
>The code does not use the XBRA method, which _is_ standard...

XBRA didn't exist yet when this snippet was captured.

>And it does not work with RAM-TOS versions, or even with the new STE or
>TT machines... (Please use the os_start entry in the _sysbase structure
>pointed to by the system variable $4f2.)

Quite correct.

>This method is not good. The 'unused' function call might be used in a
>future TOS version.
>You simply have to install a Cookie interface for the TSR. The value of
>the cookie points to an internal TSR structure, so that a DA, CPX or PRG
>can configure the TSR.

Again, the cookie jar didn't exist back then, and installing a cookie
isn't really that simple. Unfortunately, any program that wished to install
a cookie must be prepared to creat a cookie jar if one does not yet exist.
This wouldn't be a problem in itself, but if it _does_ install a cookie jar,
it has to install a reset routine to clear the cookie jar location on a
reset. Any program installing a cookie must also be prepared to install
a new jar if the current one is full. In that case, the program must copy
all the cookies to the new jar, install its own cookie, and install a
routine at the reset vector. Fun, huh?

By the way, I imagine that you know this, but some of our gentle readers
may not have played with cookies yet...

The only way is to patch the driver. To be exact: You have to add some
code, so the patch won't be that easy... there are other drivers that
will recognize the second drive (reportedly the ICD driver and CBHD).

2483. HD-Desaster

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-27 12:46:44 UTC
From: tnzoerne@faui09.informatik.uni-erlangen.de
Message-ID: <tnzoerne.675348404@faui09>
Source record: 48017

In a moment of intellectual absence I connencted my HD
in completely wrong way to the power supply, so that
logic came up on 12V DC and the motor power had only
5V DC.
The effect was none for the moment, that means, nothing
happend, and no sound was to hear.
The problem is, that the HD is now not to convince to do
anything at all, even the motor stands still (Up to now
I connected all correctly)

Does anybody know something about that ?

I've got a SEAGATE 277-N1.
On the main circuit I couldnt find a fuse or somthing like
that, so I guess I have to get a completely new main circuit ?

Someone with technical competence might give me a hint.

2484. FATs and Formatted Floppies

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-27 14:17:46 UTC
From: ralph@laas.fr
Message-ID: <RALPH.91May27161746@orion.laas.fr>
Source record: 48020

I have tried a number of different formatters, both public and
shareware. I would very much like to know *why* most of these
formatters add 5 sector FATs? There are so few that propose 3 sector
FATs!

As I understand it, GEMDOS accepts FATs with both 12-bit and 16-bit
entries. In all the floppies that I've seen, I have only seen FATs
with 12-bit entries. Here are my calculations:

```
# FAT | 12-bit || 16-bit
sectors |clusters|sectors| bytes ||cluster|sectors| bytes
1 341 682 349,184 256 512 262,144
2 682 1364 698,368 512 1024 524,288
3 1023 2046 1,047,552 768 1536 786,432
4 1364 2728 1,396,736 1024 2048 1,048,576
5 1705 3410 1,745,920 1280 2560 1,310,720
6 2046 4096 2,095,104 1536 3072 1,572,864
```

So, other than for 1.4 Mb floppy drives, wouldn't 3 sector FATs
suffice for floppies even with 84 tracks? For single-sided floppies,
I suppose that one could use 1 or 2 sector FATs.

Is the real reason hidden somewhere in the Developer documentation?
If STs would generate 3 sector FATs, then we would not have all those
FAT viruses.

Just curious,

>FATs!

You are right, 3 FAT sectors are sufficient. All the formatters
I've written generate small FATs and give you additional space
on every disk. To my knowledge, there's no special reason why the Desktop
uses a 5-sector-FAT.

If you had used the right connector, you could not have fed 12 volts to
5 volts. Well, I have done this many times in the past, but managed
everytime by sheer luck.
(1) feeding 5 V to 12 V does no hard, so forget this.
(2) feeding 12V to 5V circuit creates eternal damage to components.

Transistors, resistors and capacitors usually survive (unless they have the
specification of '8V' or something that means below 12 V). The IC's go
erratic at 5.5 V and most of them got killed at 7 V. So all you can do is
to have a LOGIC PULSER ready and test all the default signals of IC's on
the board that have been fed with 12 V. The logic pulser is a convenient
tool costing US$30 or less that tells you the logic level of IC pins by
simply touching them. Ah, you will need a TTL handbook.
If most of the affected chips are custom made chips, you cannot usually cope
because they cannot be replaced easily.

I wish you a good luck.

Source record: 48025

The standard number of sectors for FATs is 3 for each FAT on a 9-sectored 2DD floppy and the media descriptor byte is 'ff9'.
Incidentally, TOS formats the media as recommended by the 1770/1772 manual, not following the IBM nor ISO standard though this cannot result any inconvenience these days. ATARI's format is good in a way because as the controller can read the data immediately after the start of the track, the preamble can be very short, enabling the trailing GAP4 very long, allowing greater deviation in rotational speed.

2489. Re: Using Mac fonts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-28 01:00:04 UTC
From: hyc@hanauma.jpl.nasa.gov
Message-ID: <1991May28.010004.2754@jato.jpl.nasa.gov>
Source record: 48028
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

When I set about converting PD Mac fonts using NeoCept Fontz!, I had access to a nearby Mac as well (my roommate's, at the time.) I used a Mac app called Font Librarian to split up Font sets into individual files, and then MacArc to collect them into a single .ARC file. Then I just used Ymodem to transfer to the ST. (Stupid Mac doesn't have a free Zmodem that I'm aware of. Of course, this was also a couple years ago...) Unarchive the files on the ST, load into Fontz!. There's nothing particularly difficult, it is just very very tedious/time-consuming. You need to spend a great deal of time touching up the scaled bitmaps for your particular output device. The Mac fonts are generally for screen and imagewriter, which are both 72x72dpi output devices. The ST screen is 80 or 90dpi depending on how your monochrome monitor is adjusted... Fresh out of the box an SM124 gives you 90dpi (and that 1 inch black border...). If you're not too fussy, and more than a little bit lazy, like me, you can use the screen fonts directly without scaling them, just setting the proper amount of spacing.

Scaling for your printer is a big hassle, one that I only did for a select few fonts. Best advice is to take the largest available screen font, then scale that to the largest desired printer font. When that is done, it'll be less work scaling down to the smaller printer font sizes.

My biggest gripe with working with the printer was that I had no real control over the actual resolution. (Using a KXP-1091i, and the FX driver.) I really wanted to write my own GDOS printer driver for the KXP, but never took the time to do it. I guess this is now a moot point since FSMGDOS is coming out...

I did read some where that the Atari 5 sector FAT, was a Bug, should be
3 sectors, and this was going to be fixed in TOS 1.4.

But because of compatibility problems it had to be left in.

I am looking for a source of TOS 1.4 roms and can only find the 6-rom set locally. I would prefer the 2-ROM set as it would be nice to swap back to version 1.2 from time to time if there is some incompatibility with a much loved program (1 have a 2-ROM set of version 1.2).

So, where in the US could i get a copy of 2-rom TOS 1.4, maybe a place that is on internet, a place that I could quote a VISA or MASTERCARD number to, a place that doesn't mind posting the goodies to the antipidies?

Thanks in anticipation...

2493. Atari 520STE Power Supply

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-28 03:55:56 UTC
From: richard@ariel.ucs.unimelb.edu.au
Message-ID: <715@ariel.ucs.unimelb.edu.au>
Source record: 48033

Hello Atari fans...

I was asked to have a look at a friend's atari 520-STE which had died,
it had a severe power supply fault which involved the main
fuse blowing in a rather impressive manner. I am assuming at this stage
that the transformer is at fault (a resistance test seems to confirm this).
However the problem is that the transformer is a rather strange looking
beast which may well be impossible to source here in oz. I rang the
Australian parts distributer who claim that they can only supply the
power supply as a whole and they want AUS$170 for it. Now I reckon that this
is a bit steep as I can pick up a whole machine second hand for about
AUS $400.

What I was wondering was if it would be possible to source the transformer
overseas, or perhaps the whole power supply at a reasonable price. At this
stage I am open to suggestions. If anyone in Oz has any ideas
that would be even better.

Thanks in advance...

There is an exec_aes. It's called exec_os!

>The program Form_Pop makes the dialogs pop-up under the pointer, real usefull
>for Julians R.'s BigScreen...

The new `BigScreen 2' (a commercial product) installs a cookie which
contains information about the visible part of the screen. Application
and library writers can use this to `really' center their dialogues.

There is the XBRA-method for stealing vectors; it should ALLWAYS be used because it allows to detect all programs in the chain, so one can find viruses and others of that kind. In my opinion, the only cause not to use it is given in a prophylactic; so, if a program does nothing in that way, it should use XBRA.

Easiest way is to buy a SCSI-adaptor board from ICD,Inc and an ADAPTEC 4000 board (SCSI to ST506).

But I should think there must be some adaptors that handle ST506 drives directly or connects ATARI-ST's DMA socket to a standard SASI (50 pins) drive. Does anyone know a vendor of these adaptors?

As the price of a 20 MB drive is almost nil (US$20) and 40 MB SASI drives are quickly disapppearing (US$400), the cost of buying an ADAPTEC SCSI board appears to be too expensive.
Yes, a DIY project for SASI is rather easy, but I would think buying another ADAPTEC board second hand will save the trouble.

Well the 2 chip set Roms are being sold in the UK.
Check out ST-Format and ST-User Magazines for details.

You will have some small problems with the USA Roms, a few keys will
get remaped, the USA Key board is not the same, plus you will get USA
date format and 60hz as standard.

>Since you have to write a little device driver, you also have to take care
>of the media change state. If you return 2 all the time at Mediach() calls,
>TOS should not keep old information it it's caches.

If you return 2 on every call, then you could never do anything: 2 means HAS CHANGED, and all open handles on the drive are closed. Subsequent accesses with those handles would return EIHNDL (invalid handle).

Even if you return 1 and find that GEMDOS always re-reads the sectors, this will be REALLY SLOW, because TOS uses Mediach() to validate its cache buffers, and it happens A LOT in some cases. Example: for each Fsfirst/Fsnext call in a directory search, you'll get at least one Mediach() call. If you actually had to read the sector over the net for each call, it would be unbelievably slow.

I don't know a way to cache a drive from outside. You're better off using MetaDOS to catch the calls at the filesystem level rather than the BIOS level. If a call is destined for a remote filesystem you make it a remote procedure call at the top level, not the record level.

Eric, aren't you running MiNT? You already have the capability: just mount it like you do a Minix filesystem and make remote procedure calls at that level. You could even do local caching and make remote calls like, "Are my cached buffers still valid?" to reduce your net traffic.

pegram@kira.UUCP (Robert B. Pegram) writes:
>[T]he TT's VME bus is only D(ata)16(bits), A(ddress)24 (one vme
>connector), which is fine for a Mega STE, but you need D32, A32 to
>really handle an 030. I'm also not completely clear whether VME
>supports Bus mastering properly ...

The VME in a TT and a Mega STe is indeed A24/D16. In addition, it is slave-only: the VME board can't be a bus master. It is not unreasonable to suppose that a future machine from Atari might have full-sized VME with A32/D32 and full bus mastership.

I have seen at least one product where you put the TT in a card-cage and get larger-sized VME connections (6U; the TT only has 3U) but the bus is still the same. The only difference is the physical size and shape of the VME cards you can plug in. There is lots available in A24/D16, especially if you aren't limited to 3U (as the TT and Mega STe are), but as I said, the VME card(s) can't be bus master(s) in the current machines.

There are lots of hostadapters that convert SCSI to ACSI. If you want
to connect a drive to your ST, you'll better look for a way to convert
ESDI/ST506/SMD/whatever to SCSI. I know of ESDI/SCSI and ST506/SCSI
controllers, but I haven't heard anything about SMD.

2507. detecting GDOS and using vst_load_fonts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-28 19:51:58 UTC
From: steve@thelake.mn.org
Message-ID: <A1987909308@thelake.mn.org>
Source record: 47944

I'm having trouble figuring out how to use an alternate font
to draw text in a GEM window. I presume I need to check for
the existence of GDOS before calling vst_load_fonts, but
how?

I'm also getting three bombs when calling vst_load_fonts, with
AMCLITE installed and ASSIGN.SYS set up properly (or at least well
enough that GEMINI doesn't complain).

I'd like to install Gemini 9 pt inside an application program.
Do I need to search for "Gemini 9 pt" in the data returned by
vqt_name() or do I search for the filename "BAGE09.FNT"?

Code fragment follows:

```
open_vwork()
{
int i;
char tmpln[80];
handle = graf_handle( &char_w, &char_h, &box_w, &box_h);
for( i=0; i<10; work_in[i++] = 1 );
work_in[10] = 2;
v_opnvwk( work_in, &handle, work_out);
fonts_loaded = work_out[10];
sprintf(tmpln,"[1][There are %d|fonts available][OK]",fonts_loaded);
form_alert(1,tmpln);
/* note: it tells me I have one font available */
fonts_loaded = vst_load_fonts(handle,2);
/* BOOM! Three big ones and we go no further */
sprintf(tmpln,"[1][After vst_load_fonts,|there are %d|fonts available][OK]",fonts_loaded);
form_alert(1,tmpln);
if (fonts_loaded > 1)
set_font();
}

set_font()
{
/* Wouldn't it be nice if there were a font selector like the
file selector? (Volunteers?) */
int i,fontindex;
char fontname[32];
char *p = "BAGE09.FNT"; /* or should it be "Gemini 9"? */
if (form_alert(2,"[1][Load BAGE09.FNT?][Yes|No]") == 2)
return;
for (i=0;i<fonts_loaded;i++)
{
```

```
/* find the font */
fontindex = vqt_name(handle,i,fontname);
if(strnicmp(p,fontname,strlen(p))== 0)
{
/* select the font */
vst_font(handle,fontindex);
/* set the point size */
vst_point(handle,9,&char_w, &char_h, &box_w, &box_h);
return;
}
}
}
```

The Adaptec 4000A will probably be the best solution for this. This is
a ST506/SCSI controller which is also used in the original SH205.
Therefore, most software will be compatible with it.

You will also need some SCSI/ACSI hostadapter - any brand will do.
If you hook up a SCSI drive to your ST, you'll only need this
hostadapter and no separate controller, so you're right to suppose
this is much easier. It is not easier to connect an ESDI drive to
your ST - you will then need a ESDI/SCSI controller to convert
ESDI to SCSI.

It may be possible for you to obtain from atari (Fear and loathing!)
(as a 'spare part') a Megafile 30 controller board. Presuming yours isn't
DOA (as my first two were) it is a direct ACSI-RLL adapter. Now, lots
of people will jump on me and say 'but the NEC is only MFM' - this is
true - however I have had a very good run with NEC harddisks, in
particular with my 3142, which has been running RLL for about a year
on a daily basis with no problems whatsoever. The 20MB unit may do the same.
Find someone who will let you dissect their Megafile and try it :)

Good Luck!

Matthew

2514. Atari HD hostadapters/drivers.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-29 14:28:12 UTC
From: mbaker@ucs.adelaide.edu.au
Message-ID: <3444@sirius.ucs.adelaide.edu.au>
Source record: 47950
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Greetings all!

I'm looking for some information on the available host adapters for the ST, and also driver s/w.

Currently I am running a Megafile 30 adapter board and an NEC D3142 drive. Someone I know is looking for an RLL controller to talk to an RLL CDC wren, and I want to sell my controller to this person.

This places me in a difficult position: I need to find a new controller.

My current unit took me 3 months and untold hassles with certain Oz atari techs, and I don't really want to try this again.

An well, I have my eyes on another 3142, with which I hope to add a minix filesystem to my machine.

Thus, I am seeking a hostadapter which will run RLL : the only possibilites seem to me to be:

ICD + Adaptec 4000A.

Supra. (is this ACSI <-> RLL or ACSI <-> SCSI???)

Berkley Microsystems. (again, to what?? RLL? SCSI?)

Are there other hostadapters available??
Are they any good??
Costs??

Please, being hereunder in Oz, can I have some addresses for the _manufacturer_ or a dealer that will export here?

With regards to driver s/w, I understand that the Atari HDI will not support more than one drive per LUN. - how about the Supra/ICD/Berkley drivers?

How about Claus' driver (CBHD) - cost, language, etc...

Many thanks all.

Matthew.

$20 if it is MFM and ST506. The lowest end of hard disks here in Japan (
and maybe in US) is 40 MB SCSI, which costs US$400.00 with cables, power
supply and casing etc. 40 MB ST506 disks still cost $100 because some people
like myself already own ADAPTEC SCSI-ST506 cards and can simply use them
as the second drive. But as ADAPTEC cards cost $150 here and so do the
power supply and the casings, old and slow and small-capacity and funny
disks cannot be sold to resellers but to junk shops where people will buy
the casings and the power supply but not the bare drives.
I use those cheap disks as a backup meadia by using as the second drive in
my MEGAFILE30 (Gee, the first drive is now 66 MB thanks to RLL and 23 ms).
I think this will happen in UK very soon or never happen at all, simply
by-passing the era of a 70-ms-MFM-ST506-20MB disks being very popular.

From: cshera@uta.fi
Message-ID: <2824@kielo.uta.fi>
Source record: 47891

Hello !

I recently read some books of Atari ST internals by Abacus
and found some odd things I hope someone can explain to me.

1) set color representation, opcode 14 trap #2
Intensity of red, green and blue can have values from 0 to 1000.
What is done to this information ? I know it somehow ends up to
video shifter registers where intensity can range from 0 to 7.

2) open workstation, opcode 1 trap #2
intin(0) Device identification, given on loading Device Driver
contrl(6) Device identifier
What these two parametres should be ? I suppose this is a GDOS
function to load a device driver from GIOS. It is said that it won't
work because of missing device drivers. Can I make one and put it
into GIOS (how) ?

3) previous function returns among other things screen resolution and
number of colours available. How these two things are handled in Atari ?
How electronic beam inside tv or monitor knows that this time it
is supposed to plot 640 times per line insted of 320 it did last month
or to draw twice as many lines per screen as it did last time ?

With my stumbling english I think I learned that colours are produced
by MMU and SHIFTER together. In most odd way I think. Is it usual
among computers to have they video-RAM fullfilled with colour indexes
instead of their RGB-values ? If so, what's wrong with latter case ?
It wouldn't need any video shifter registers to limit colours to 16.

Any help aprpriapro... eh, valuated high.
Thank you in advance, curiosity is killing me.

If this is so, why should I use the cooking jar? I guess there are many people like me, who ocasionally write a program which needs to steal a vector. If Atari refuses to make the specification of the cooking jar PD, it is better to use the XBRA standard, which is well documented and PD.
I don't understand why Atari releases the "how to steal a vector" specification only to registered developers. Is this to ``protect'' commercial developers against PD software? I think this is bad policy, because it makes people write badly behaving programs.
I really need to write a vector stealing program myself, since there are no programs supporting my SilentWriter LC-800, and I am not going to hire a registered developer to write a printer driver for it.
When I first wrote a program which needed to steal a vector, I first disassembled a few PD programs, to see how they did it. Then I just imitated this. Now I have got the XBRA specification, with an example using it in Turbo C, and my vector-stealing programs behave correctly with respect to XBRA.

>PD.

Ooops... It's supposed to be the "COOKIE JAR" not cooking... :-)

The cookie jar is an attempt to allow resident programs to leave a memory
resident 'cookie' uniquely identifying that application for any other
application which is aware of it, in one common location. Then, a longword
following the unique ID can point to some application specific routine/
structure/whatever, or the longword can mean something itself.

The 'cookies' are stored in a table which you can add/delete or change.

>I don't understand why Atari releases the "how to steal a vector"
>specification only to registered developers. Is this to ``protect''

You misunderstood me, so let me make myself clearer:

ATARI DID NOT RELEASE THE 11 COMMANDMENTS FOR TAKING VECTORS!

Charles F. Johnson (CodeHead and Little Green Footballs Software) did!
As far as I know, Atari has never sanctioned that methods described, altho
the methods described are widely accepted and practiced. I would GUESS that
since Atari is aware of these practices, they will attempt to keep them
working as long as possible in all future TOS/GEM revisions (IMHO).

2527. Sleeping GEM

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-30 13:48:47 UTC
From: hofmann@cbnewse.att.com
Message-ID: <1991May30.134847.949@cbnewse.att.com>
Source record: 47964
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have written a GEM application that launches a long running
application, writting text output to one window and graphs to
other windows. This works fine, except that - after running awhile -
the computer halts. It stays halted until the mouse is moved.
The mouse pointer is converted to a bee while the application is
running and back to a pointer when it re-enters the event_multi loop.
When the program locks up, the mouse pointer is still a bee. I am
running this on a Mega ST2, TOS 1.4, Viking Moniterm monitor.
Is this a known problem? Are there workarounds?

Any insight into this problem would be appreciated!

I've had a megafile 30 for about a year, and the only complaint
I've had is the loud fan. Is it really needed, or will the
drive run cool enough without it? Are there any ways to quiet the
fan, maybe replacing it with a quieter one?

THanks,
Chris

2529. lharc

Newsgroup: comp.sys.atari.st.tech
Date: 1991-05-31 04:59:12 UTC
From: swood@vela.acs.oakland.edu
Message-ID: <6652@vela.acs.oakland.edu>
Source record: 47965

I just pulled a couple of versions of lharc off of the archive at umich, but I have been having a hard time getting it to work on all files. I keep either running into CRC errors, or I just get "no file" when I try to extract an archive that I have downloaded. I have run into this with files that have been created on the systems here at OU as well as from abroad.

What is the best version of lharc, and where can I find it? And what may be causing these things to have such a hard time?

That's happening because there is an unfortunate "double-standard"
(forgive the pun) with LHARC - i.e. two standards exist. My best advice
is for you to get LHARC060 (Jon Webb & Bart Van Herk) and
LZH11319 (Haruyashu Yoshizaki) - if one doesn't work I can about 99%
guarantee you the other one will (I've run into the same problem
before). You can find both files at atari.archive.umich.edu in
the /atari/archivers directory. And I'd recommend getting ARCSHL25 as
well - it lets you set up a Main and Secondary choices for the LZH (as
well as ARC) programs - that way you could switch between them rather
easily.

Maybe one of these guys will come up with a version that handles
BOTH standards (A "dual" standard program)...

Atari UK have said that it is OK for developers to talk about the contents of 'release notes'. The definition for the Cookie Jar protocol is in the STE TOS Release Notes so I guess we can talk away ...

At first I thought the same and replaced a better fan, which made no
difference (human feel the noise is reduced to half when it is reduced to
one tenth). I then added a couple of diodes along the 12 V line to the fan
to reduce the voltage and turn the fan slower. This didn't make a difference
either. I then bought another 5.25" disk second hand (66 MB at US$150) which
is reputed to be the least noisy. The noise has been reduced to half, but
it was still roaring!
I then bought a 3.5" disk of the same specification at the same price. The
noise has been reduced quite substantially now. But I must say it is still
noisier than ordinary 104 MB SCSI drives.

The megafile30's original drive was a seagate thing and got heated very
easily. People sometimes sticks a very think fan on the drive mechanism
directly,but the casing of megafile30 does not allow this.

A warining: a 3.5" drive cannot be replaced on the 5.25" mounting.

I am registered developer and I haven't heard squat about any updates
since TOS 1.4 and SALAD. Hell, I had to ask for the TOS 1.4 notes from
Atari Canada which turned out to be photo copies of reduced photo copies
which are so blurred that I have trouble reading them with a magnifying
glass.

I would love to know if there has been a full documentation update
since TOS 1.4 that also includes information on TRAP #2 and all the
other extras that have been been coming down the net from time to time.

Allan or Ken, do either of you have any comment on the current state
of the developer package? I feel alone up here in the north country
and Atari Canada is only one hour east of Waterloo yet they never
seem to have mail-outs or current information when I phone.

Huh? The cookie jar is documented in the STE TOS Release Notes, and as far
as I know, it is _allowed_ to publish informations found in recent release
notes (as opposed to documentation about future operating system features).

>/* BOOM! Three big ones and we go no further */

(1) make it: fonts_loaded += vst_load_fonts (handle, ...); You get the
number of _additional_ fonts.
(2) call vq_gdos() first
(3) No, I really don't know what the problem could be.

Hello Chris!
I think you need the fan, because those Seagate drives in the MEGAFILE 30
can get hot. Here in Germany are kit's aviable to make the fan not so loud.
First of all you can remove the lattice behind the fan. I heard of some
people that solder a resistor in the power connection of the fan.
I have a little kit, that turns the fan only on, if it is to hot in the
drive. You need nothing to solder for that one.

Greetings, Olaf

Can someone please mail me some details about how to get developers documentation and exactly what you got from Atari?

I assume the non-disclosure agreement is still here. However, (more important to me at the moment) do you still have to have developed (or be in the process of developing) a commerical product to be an "official developer" and continue to do so to keep that status?

(I wrote to them about a year or two ago. Unfortunately, I have since lost the address. I assume things have changed...)

Message-ID: <LA_CARLE.91May31155532@sol.brispoly.ac.uk>
Source record: 47981

Hello World (to coin a phrase)

I'm using MiNT 0.8, with the Korn Shell (0.4) from a.a.u.e. I've just come across what seems to be quite an obscure but disastrous bug in the file match. What I had was a directory which (for reasons I would rather not try to explain) got a file called ./compress.ttp in it (yup ./ and all). Its on a Minix FS partition. When I tried to do ESC ESC to file match a filename in that directory, the shell (or MiNT?) did what I can only assume is a memory fill (because the screen was covered in an odd pattern after a few secs). Oh it also took out MiNT and crashed the machine.

Has anyone else seen this and is there a fix (apart from not repeating the exercise).

I am attempting to run BinkleyTerm on a Supramodem 2400.
For the modem init: field, I am using AT &D3 &S0=0|
However, the modem refuses to dial out with this code.
Any ideas/help appreciated.

I find that the newer versions of lharc don't seem to be compatable with the unix lharc... the version I use is very slow, its like v1.1 or something like that (i think it says its based on v1.13c or something) anyways, try an old one it will probablly work for you (and be horribly slow, but thats another story)

I have been trying to get GDOS drivers for my HP Deskjet for "ever"
it seems, and now have given up the search (No, I haven't ordered one from
Migraph, please read rest of note) to await the arrival of FSM-GDOS.

Questions:
1) When will it be relesed ?

2) Who will handle distribution (Atari Directly, or through dealers, mail
order, ...)?

3) What will it cost, and will it include (as I have heard rumoured) drivers
for most printers including the HP DeskJet (original version)?

4) Can I get it now by buying Goldeaf's Wordflair II?

5) Will this guy ever run out of questions? Why ask why? Why is the sky blue....

Thanks in advance for whatever information you can provide!
I would assume posting replies should be appropriate, since I am sure
that many would like to hear more details about FSM-GDOS!!!!

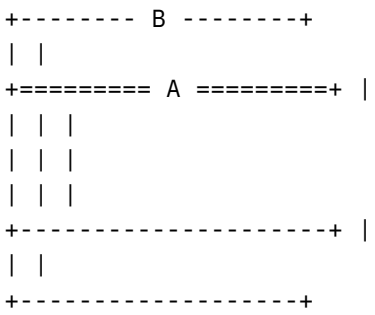
From: jfbruno@rodan.acs.syr.edu
Message-ID: <1991Jun1.030346.18971@rodan.acs.syr.edu>
Source record: 47895

I'm using evnt_multi() to check for window redraw messages, and everything works as expected except for this one situation:

Say you have 2 overlapping windows "A" and "B" like this:



If I slide "A" to the left by a little bit, I get a redraw message for window "B" specifying the newly uncovered region that needs to be redrawn. This works fine and is as expected.

However, If I click on "B" to bring it to the top, I get a message specifying that the entire window area of "B" needs redrawing. Obviously, parts of "B" that are already visible don't need to be redrawn, but I get a large "rect". Is this the way ST GEM is supposed to treat bringing a window to the top??

Well you could be able to help me.
I am unable to get Arcshl25 to work with LZH11318,
this is the latest one that I have, but the Problem is with Folders/Paths,
there is a option with arcshl25 for LZH11316,
but so far it does nothing, the arcshell still sends a 'z' parameter for
the directory option.

So far I am unable to LZH Files with Folders/Paths, with this combination
also there seems to be a limite with LZH of only 2 folders deep,
is this correct ?

Also I don't think there is a Directory/Folder Option with LHAR060.

I am having a terrible time reading the joystick port (1 and 2) from
assembly language. If you have an assembly routine that will do this, could yo
please post it or send it to me?

Thanks in Advance!

2554. Mint and minix filesystem.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-02 00:30:44 UTC
From: erlingh@sigyn.idt.unit.no
Message-ID: <ERLINGH.91Jun2023044@sigyn.idt.unit.no>
Source record: 47892

I'm having trouble with mint not recognizing my minix partitions. I currently have mint 0.8 compiled with the newest libraries and include files. I wouldn't consider this too strange, if it wasn't for the fact that it recognizes floppies... Also, the minit program worked just fine, but as soon as I try to read the minix-partition, no way !
Btw, my harddisk is formatted with ahdi 3.1, but without extended partitions. It's an atari megafile 60.
So to a slightly different question. When using bash or ksh from MiNt, every now and then the shell locks up. It doesn't crash, it just waits for something, and I can get it to continue if I send it a sigcont. Now this is no big crisis if I run mgr, cause then I can send the blocking shell a signal from another shell. However, if I use any of these shells standalone and they lock up, I can't do anything but press ctrl-alt-delete. I guess it has to be something wrong with these shells, because it has happened in all versions of mint since 0.6, and it happens on both my TT and my TOS 1.4 equipped mega-ST.
It never happens with init.prg, but with ksh or bash it happens after about 50 commands (sometimes sooner/later/never).
Anyone else experienced this ??? anyone got any ideas of what is happening ?
Help !

2555. Re: monitor break down

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-02 00:42:32 UTC
From: ytsuji@wucc.waseda.ac.jp
Message-ID: <5776@wucc.waseda.ac.jp>
Source record: 47893

I have just thought of an important preventive measure to cope with
the monitor break down that is very likely to happen to us all very
soon.
Make a diskette with an auto-start program that prints
"Your monitor alone has broken down\n"
"Do you hear me?\n"
to the printer and then prints
"\07\07\07"
to the console.

I thought this simple idea was too good to be kept private.

2556. Moniterm 19" Monitor For Sale: Reduced!

>to extract an archive that I have downloaded. I have run into this

I tried using a shell (arcshell2.5) but gave up because anytime you
specified more than just "extract" or "list", it would get lharc confused and
it would think you were looking for "xs.lzh" instead of using it as the command
which allows "extract" and "hold screen". I gave up using the shell and now
use lharc from the ttp command line. If you are using a shell, try removing
the "extras" that you can do with it and just have it "extract". It might
clear up the problem. Or if you want to use the command line, just look in
the docs that should come with the lharc - it should have the commands in an
English (and German) doc. If you want, "x <filename>" should unarc just fine
from the command line (clicking on the ttp file).

>
>What is the best version of lharc, and where can I find it? And what may
>be causing these things to have such a hard time?

I think the latest lharc out is lzh11319.lzh (that's funny - it's lharced!)
and it's up on atari.archive. BTW, what was/is the difference between lzh11316
and lzh11319? I can't read German or I might have gotten it from the docs...

2558. Re: detecting GDOS and using vst_load_fonts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-02 21:50:17 UTC
From: bjoern@drdhh.hanse.de
Message-ID: <3269.11.27@drdhh.hanse.de>
Source record: 47897

From article <A1987909308@thelake.mn.org>, by steve@thelake.mn.org (Steve Yelvington):
> fonts_loaded = vst_load_fonts(handle,2);
> /* BOOM! Three big ones and we go no further */

I think you should use 0 instead of 2 because the parameter 'select' is
reserved in Atari-GEM and has to be zero.

I've once written a 'Device Info' program in Turbo-C - you give a device
number from assign.sys - if the devno is equivalent to the value returned
by graf_handle() it will open a virtual workstation otherwise it'll load
the driver for a physical one. The program checks for GDOS available and
decides whether to open phys_wk/load_fonts or not. It also prints a font-
list. Be aware: Some drivers (printer, plotter...) use different values
for non-existent or default fonts, the tests performed in di.c are not
taken from any documentation, they ayre just what I figured out.

It uses a Turbo-C library function called vq_gdos() which is official and
implemented as follows:

```
vq_gdos:
MOVEQ.L #-$02,D0
TRAP #2
ADDQ.W #2,D0
RTS
```

I append the source for this little program because I think it is of
general interest:

```
/*
* device info - display information about vdi devices / Turbo-C 2.00
* Note: GEM arrays don't hae to be declared when using TC
*
* ANY NOTES, TIPS, HINTS, BUGS, BUGFIXES -> bjoern@drdhh.hanse.de
* thanks
*/

#include <vdi.h>
#include <aes.h>
#include <stdio.h>

main(void)
{
int gh,h,i,dev,ret;
int in[11],out[57];
int p[10],numfnt;
char fnt[32];
```

```
appl_init();

gh=h=graf_handle(&i,&i,&i,&i);

printf("Enter device number: ");
scanf("%d\n",&dev);

if(dev!=gh)
{
if(!vq_gdos())
{
printf("Can't open physical workstations without GDOS\n");
appl_exit();
return 1;
}
}

in[0]=dev;
for(i=1;i<10;in[i++]=1);
in[10] = 2;

(dev==gh ? v_opnvwk : v_opnwk)(in,&h,out);

if(!h)
{
printf("can't open workstation\n");
appl_exit();
return 1;
}

printf("Handle is %d\n",h);
printf("Physical Resolution is %u * %u, %d colors\n",
out[0]+1,out[1]+1,out[13]);
printf("Pixels are %d um * %d um\n",out[3],out[4]);

if(vq_gdos())
{
printf("Loading fonts...\n");
numfnt=vst_load_fonts(h,0);
printf("Loaded %d font%s.\n",numfnt,numfnt==1 ? "" : "s");

printf("Available fonts:\n");
for(i=1;i<=numfnt+1;++i)
{
ret=vqt_name(h,i,fnt);

if(!(i>1 && (ret==1 || ret==-1)))
printf("%2d. ID %3d Name: %-32.32s\n",i,ret,fnt);
}

vst_unload_fonts(h,0);
}
else
printf("No fonts without GDOS\n");
```

```
(dev==gh ? v_clsvwk : v_clswk)(h);
appl_exit();
return 0;
}
```

Hope that helps,
Bjoern

>

I have that kit, too. Or rather: I _had_ it. I disconnected it,
because since it was installed, I had some troubles with the disk.

When the disk was used for more than four hours the day before,
it wouldn't start up again. I nedd to shake the entire disk quite
roughly to get it rotating again. I know some day this will have
disastrous effects...

I blame the fan thermostate for this problem. Unfortunately, although
I disconnected it, I have still this startup problem.
I wouldnt recommend a fan thermostate.

From: rmacgreg@cs.strath.ac.uk
Message-ID: <6609@baird.cs.strath.ac.uk>
Source record: 47904

Help! I am looking for a method of putting 2 processes in touch with each other. More specifically, I want to be able to find out an unrelated processes process number.

I am working along the following lines:

I want to install (or not as I wish) a number of DA's which can then communicate with each other and the main program running at the time via GEM's message passing system.

I can get the message passing bit going fine, but getting the process ID of another process is different...

Please reply via email to either of the addresses below as I'm in my exams just now so I'll miss any posted replies.

PS: It must work by using documented methods available on ALL versions of TOS.

Note; you can Program Arcshell 2.5 to send any strings you like,
when selecting the Extract etc, hold down thw Alt key, this will give
you a option box you can put in the string that you wan't, the next
time you use it, just hold the Alt Key down to give you that Option,
problem is the Programble options are not saved..
also Arcshell 2.5 has a option for lzh11316 , but does not do a thing,
as it still send a 'z' for the directory option..

2566. Tape Streamer?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-03 17:16:21 UTC
From: e89dh@rigel.efd.lth.se
Message-ID: <1991Jun3.171621.5659@lth.se>
Source record: 47905

Is there anybody who knows anything about tapestreamers for the ST?
I recently got one SCSI-komp. surplus and was thinking of getting
one of the german interfaces, is there any software avalible?, any PD?
any known problems? Please EMAIL me since I wont be able to read news
during the vacations!

David Hultgren LTH.

2567. WANTED: CAD 3-D 2.0 & Computer Eyes/Digispec formats

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-03 18:33:02 UTC
From: gknauss@sdcc13.ucsd.edu
Message-ID: <20097@sdcc6.ucsd.edu>
Source record: 47907
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Does anybody have a listing of the CAD 3-D file format? (And I'm still looking for the Computer Eyes 24-bit raw format, as well.) I looked at atari.archive, but couldn't find any information... Any help will get my first child named after you.

OK, OK. I'm just kidding...

>Why not buy the the Level 2 Developers Pack, about $125 US from what I here
>this is worth every cent, at least this is one thing that Atari has
>now done right, Thanks Atari..

No thanks Atari Canada. About two years ago now, I was becoming seriously interested in developing for my ST on my off hours, and sent away to Atari Canada requesting information on obtaining developer kits of *any* sort.

I received back a mailer thanking me for my request and requesting I fill in about a 3 page prospectus on my business plans (i.e., exactly what product I intended to develop, in what marketplace, what time frame, etc.). Well, being a bit taken aback, I thought for a while and replied that I was a professional software developer with a university degree in CS and had several ideas for products but couldn't commit to everything they asked for.

After mailing and waiting some two weeks, I received a "sorry, but we must only give developer kits to those who can completely specify their plans, etc but buy the Sybex books if you need information." PHOOEY! Needless to say I wasn't impressed; I was willing to pay the $$ for the kit and to do some development work on the ST, but they shot me dead before I had the chance.

The moral: Not all Atari outfits are created equal. I knew at the time that the US folks were getting developer packs for their cost with no song and dance.

Sigh Live and learn, Atari!

>>please post it or send it to me?
>>
> I would also like to see this posted as Atari ST internals doesn't make
>this clear enough for me..
```

Okay, I'll post my code. Note that I think this WORKS (on tos 1.0, and 1.4 so far) but I think it may be wrong (because I am assuming "a0" is the input parameter, whereas I expect it would be on the stack).

This is my code:

First, the packet handler:

```
JoyDo:
movem.l d0/a1,-(sp)
move.l #Stick,a1 ; Location of the place you want to
move.w 1(a0),d0 ; store data (it is "byte Stick[2]")
cmp.b #$FF,(a0) ; (or VAR Stick:ARRAY [0..1] OF CHAR)
beq Joy1
lsr.w #8,d0
add.l #1,a1
Joy1:
move.b d0,(a1)
movem.l (sp)+,d0/a1
rts
```

That isn't my actual code - I decode the directions and trigger - but it shows what you want.

Now the rest (which you can probably work out already)... It's in Modula-2, so anyone who knows Pascal can work it out.

```
TYPE KeyVectors=POINTER TO
RECORD
midivec,vkbderr,vmierr,statvec,
mousevec,clockvec,joyvec:ADDRESS
END;

VAR OldJoy:ADDRESS;

PROCEDURE InitJoysticks;

VAR KV:KeyVectors;
Cmd:CHAR;
```

```
BEGIN
Cmd:=024C; (* 20 decimal, 14 hex *)
ikbdws(ADR(Cmd),0)
KV:=kbdvbase();
OldJoy:=KV^.joyvec;
KV^.joyvec:=ADDRESS(JoyDo);
END InitJoysticks;

PROCEDURE TermJoysticks;

VAR KV:KeyVectors;
Cmd:CHAR;

BEGIN
Cmd:=010C; (* 8 decimal/hex *)
ikbdws(ADR(Cmd),0);
KV:=kbdvbase();
KV^.joyvec:=OldJoy;
END TermJoysticks;
```

Finally, I appologise if this is ugly or incorrect, all I have seen of this module for a while is:

```
DEFINITION MODULE Joysticks;

(* Supplies access to the two joystick ports *)

TYPE JoystickDirection=(none,up,down,updown,
left,upleft,downleft,updownleft,
right,upright,downright,updownright,
leftright,upleftright,downleftright,
updownleftright);

JoystickRecord= RECORD
Up,Down,Left,Right,Trigger:BOOLEAN;
END;

(* A variety of formats... *)

VAR Joystick:ARRAY [0..1] OF JoystickRecord;
Stick:ARRAY [0..1] OF JoystickDirection;
Trig:ARRAY [0..1] OF BOOLEAN;

XStick:ARRAY JoystickDirection OF INTEGER;
YStick:ARRAY JoystickDirection OF INTEGER;

PROCEDURE InitJoysticks;
(* Enables both joysticks, disables mouse movement *)

PROCEDURE TermJoysticks;
(* Restores normal mouse action, disables joysticks *)

(* InitJoysticks is automatically done at initialisation
TermJoysticks is automatically done upon termination *)

END Joysticks.
```

Long live M2,
Ciao,
Warwick.

I wouldn't be so quick to blame the kit on this problem. I see SO many
disks come in where I work that have this problem, where the spindle sticks.
It happens on low capacity drives (especialy 3 1/2" drives like the ST125(N))
a lot. No one has been able to tell me how to fix this problem (if it is
fixable), but I have found that by manually rotating the spindle frees it up
a lot safer than shaking it.

This may not apply, but I had a SH205 hardrive in a Mega ST box. I, too, was
getting pissed off by the loud fan. I open it and noticed that the hand was not bolted to
anything but it just sits into a slot. I then put some blue-tac so
that it will stick to one of the side walls to stop it vibrating against the
surrounding wall or stop it jumping around in its slot. I was quite amaze as to
the amount of noise being removed.
I have not seen the inside of a megafile 30, but I assume that it would be the
same.
The blue-tac material is some stuff that will adhere two piece of material but
with the ability to separate them later.

The 0-1000 range is used in VDI to support other devices which have more
colors. They are simply mapped to a 0-7 range.

> 2) open workstation, opcode 1 trap #2
> intin(0) Device identification, given on loading Device Driver
> contrl(6) Device identifier

> function to load a device driver from GIOS. It is said that it won't
> work because of missing device drivers. Can I make one and put it
> into GIOS (how) ?

You need GDOS in your AUTO-folder (i.e. distributed with Gemini).
Then you can use this call to load one of the .sys files by a number
givwen in your assign.sys file which is read by gdos.
GDOS will then load your driver (i.e. EPSONFX.SYS) and use it for
VDI calls you perform on the handle given by v_opnwk.

Writing device drivers is a bit more of work, you have to write the complete
VDI functionality. You may hook in a basic module distributed by atari to
developers (devdvr kit) but that library is AWFULLY slow.

If you want more information on device drivers, I could translate a german
version of a text I one wrote for somebody.

> 3) previous function returns among other things screen resolution and

> How electronic beam inside tv or monitor knows that this time it
> is supposed to plot 640 times per line insted of 320 it did last month
> or to draw twice as many lines per screen as it did last time ?

Has nothing to do with your monitor. $ff8260 (shifter) determines what kind
of video-beam control is generated.

> With my stumbling english I think I learned that colours are produced
> by MMU and SHIFTER together. In most odd way I think. Is it usual
> among computers to have they video-RAM fullfilled with colour indexes
> instead of their RGB-values ? If so, what's wrong with latter case ?
> It wouldn't need any video shifter registers to limit colours to 16.

MMU has nothing to do with colors. Screen memory indexes the color regs in
the shifter.

2581. Hardware Project: RAM disk

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-04 20:51:25 UTC
From: es2a+@andrew.cmu.edu
Message-ID: <QcGzpBG00UgI9Yw5kd@andrew.cmu.edu>
Source record: 47917

I've been considering building some sort of RAM disk for my 4 Mb
1040STE, and was wondering if anyone else out there would be similarly
interested...

Necessary components of said RAM disk:

* use of SIMMs
* support of at least 2 Mb in a minimum construction
* support for different sized SIMMs (256K, 1Meg, 4Meg)
* as cheap as possible

I have considered several different lines of attack, including the following:

* Cartridge port interface, similar to the Alpha Systems RAMdisk. This
has the disadvantage of being slow, and very non-portable to non-ST
systems.

* Serial interface, possibly with a native CPU. This would definitely
be slow, even at 19200, but would be supremely portable to non-ST
systems.

* SCSI interface, possibly with a native CPU. I imagine that this
would be rather expensive to build, due to the cost of SCSI chipsets and
an ACSI->SCSI converter board. It would, however, be useful on non-ST
systems. Throughput would probably be not bad.

* ACSI interface, possibly with a native CPU. This would probably be
easier and cheaper to build than the SCSI version, but would be much
less useful on non-STs.

* CPU replacement board. Basically, replace the CPU with a CPU+memory
daughterboard. Fast, but again, not useful on non-STs.

I'd like to look at these possibilities in more detail, and try to
get at the relative costs and strengths of each of these, then build
something. Is there anyone else out there who would be interested in
working on this? I'm sort of surprised that there are no commercial
SCSI RAMdisks on the market. Or am I missing them? Any comments are
welcome, as right now I don't have the hardware knowledge to build one
of these or the software knowledge to write the drivers.

Hi again
Can anyone provide me with a copy of the english doc's for midi maze 2
or maybe where I can get them via ftp

thanks
Nick Coyne

2584. English docs for Turbo Assember?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-05 01:37:59 UTC
From: chu@acsu.buffalo.edu
Message-ID: <78893@eerie.acsu.Buffalo.EDU>
Source record: 47921

I just got and unpacked turboass.lzh from atari.archive and it certainly looks like a very comprehensive package (and the graphics version of sokoban is good too!). However, I don't know any German so I was wondering if English docs are available anywhere?

Please reply by e-mail. Thanks!

john
chu@acsu.buffalo.edu

Sounds like a fun and usefull project.

I think using the DMA port is the way to go. I wonder what it would take to make it be either ACSI or SCSI depending on how you populate the board. Then you could build it to connect right to the DMA port but if you ever wanted to switch to a different computer you could just change a few components and voila.

>welcome, as right now I don't have the hardware knowledge to build one
>of these or the software knowledge to write the drivers.
Hummm... You don't have any software/hardware design experience? Or just not in these areas? If it's the former then I agree with Mathew that you may want to start with a few (a bunch) of simpler projects.

(I'm posting rather than mailing because I think this has potential to be
an ST topic)

From article <QcGzpBG00UgI9Yw5kd@andrew.cmu.edu>, by es2a+@andrew.cmu.edu (Eric
Stuyvesant):
>
> I've been considering building some sort of RAM disk for my 4 Mb
> 1040STE, and was wondering if anyone else out there would be similarly
> interested...

If it works, I might build one (huge :)

> Necessary components of said RAM disk:
>
> * use of SIMMs
- SIPs would result in a slightly cheaper device. Use machine pin socket strip
instead of $IMM $ocket$
> * support of at least 2 Mb in a minimum construction
> * support for different sized SIMMs (256K, 1Meg, 4Meg)
> * as cheap as possible
-A major hassle with _anything_ using DRAMS is the refresh timing. The
TI 746301 is the only DRAM controller I have had much experience with, and
that was extremely frustrating. Hence I use SRAMS in all my projects. :)
>
> * Cartridge port interface, similar to the Alpha Systems RAMdisk. This
> has the disadvantage of being slow, and very non-portable to non-ST
> systems.

Not necessarily slow, but inconvenient. Means a large box stuck to the side of
the machine.

>
> * Serial interface, possibly with a native CPU. This would definitely
> be slow, even at 19200, but would be supremely portable to non-ST
> systems.

Considered building a similar system using an 8086/1772 to use my old ss
floppy drive - problems were with the speed as you suggest. Lousy thruput.

> * SCSI interface, possibly with a native CPU. I imagine that this
> would be rather expensive to build, due to the cost of SCSI chipsets and
> an ACSI->SCSI converter board. It would, however, be useful on non-ST
> systems. Throughput would probably be not bad.
Native CPU more or less essential, (68000 series (eg 010, 070) weould be good)
The NCR 5380 - SCSI chip, is not very expensive. Easy to talk to as well.
>

> * ACSI interface, possibly with a native CPU. This would probably be
> easier and cheaper to build than the SCSI version, but would be much
> less useful on non-STs.

True, less useful. Easier to talk, can do it all without an ACSI chip
really (my developmental network adapter uses ACSI for speed - MIDI is
way too slow.)
>
> * CPU replacement board. Basically, replace the CPU with a CPU+memory
> daughterboard. Fast, but again, not useful on non-STs.

Not worth the effort. Way too complicated, and not much room in an ST.

> I'd like to look at these possibilities in more detail, and try to
> get at the relative costs and strengths of each of these, then build
> something. Is there anyone else out there who would be interested in

2591. HD problem of a different color

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-05 14:13:20 UTC
From: oddjob@oz.plymouth.edu
Message-ID: <ODDJOB.91Jun5101316@oz.oz.plymouth.edu>
Source record: 47926

It's a long story so I won't get into it.... BUT my old Supra HD has become a ROD (Read-Only-Device). I'm getting a new harddrive from Toad Computers (Should be in the mail....) to replace it.

Waht I would like to do is connect the old HD to the new HD so I can copy the 25+megs from the old HD to the new HD.
Q: Is it possible to connect two hard drives formatted by completely different drivers when using one driver ??
[
i.e..... my old HD is formatted with Supra software & uses a Supra driver. My new drive will use a different driver (???). Can I connect the Supra drive to the Toad drive using the Toad HD driver and still access the files on it ? I do have floppy copies of MOST of the files (I ran out of floppies backing up my Minix partitions.... but got everything else)
]
The point is --> I don't really want to restore my files from floppy when i have a HD that can be read from.....

{-email answers might be best.....-}
Thanx

From article <1991May31.191105.13736@lonex.radc.af.mil>, by longj@lonex.radc.af.mil (Jeffrey K. Long):
> I have been trying to get GDOS drivers for my HP Deskjet for "ever"
> it seems, and now have given up the search (No, I haven't ordered one from
> Migraph, please read rest of note) to await the arrival of FSM-GDOS.
>
> Questions:
> 1) When will it be relesed ?

On past performance: much later than you want, later than you expect, and a bit later than you'd dared to guess when, taking into account past performance, you were being most pessimistic.

>
> 2) Who will handle distribution (Atari Directly, or through dealers, mail
> order, ...)?

No doubt this will differ from country to country, and Atari UK will try to handle it themselves, then spend a year trying to decide whether to sell it or give it away (based on their treatment of the Epson emulator for the SLM804 and the time it took them to release the presentation graphics program Hyperchart. By the way, Atari UK still sells v1.0 of the Epson emulator, whereas Atari USA gives away v1.31. I know which I use, and I'm sorry I bought the UK product).

> 3) What will it cost, and will it include (as I have heard rumoured) drivers
> for most printers including the HP DeskJet (original version)?

See above. It would, of course, be sensible to include Deskjet drivers, but if space is tight on the disk, then an SMM124 (Atari dot matrix printer, if I've remembered the number correctly) driver might win out.

> 4) Can I get it now by buying Goldeaf's Wordflair II?

I don't know, but I bet a) they'd like to bundle it, and b) the Tramiels won't let them even though the software engineers have had it ready for a while.

> 5) Will this guy ever run out of questions? Why ask why? Why is the sky blue....

On the last question, read 'The Cuckoo's Egg'. Some professor once asked Cliff Stoll the same question in an astronomy exam and had him sweating for hours over the answer.

Wouldn't it be nice if Atari were to prove me wrong on 1-4 above?

I have tried to use mint08 with my Matrix C32 graphics card.
It is working fine until I tried to start GEM. It gives some
kind of error messand rebooteboots so quicy that I can not
read the error message.

The GEM works fine with the normal screen. But even then
there is same problem if I start the graphics card in
so called "dual mode". So I think there is a little problem
with the driver of the C32-card. Does anyone have a solution?

Can somebody say, if ite possible to integrate
GEMINI and MINT? I would like to use TOS-programs in
that console window. I was testing some pgrams and
they seem to write to console window. It was quite funny,
but it was not perfect. (I was using BGACC).

I have just thought of an important preventive measure to cope with
the monitor break down that is very likely to happen to us all very
soon.
Make a diskette with an auto-start program that prints
"Your monitor alone has broken down\n"
"Do you hear me?\n"
to the printer and then prints
"\07\07\07"
to the console.

I thought this simple idea was too good to be kept private.

But the sound of the bell comes out of the monitor, so it won't work
if your printer is off and the monitor is completely dead. Otherwise a
good idea.

2601. RECORDING MIDI DATA ON THE ATARI ST (while allowing mouse movement)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-05 23:24:54 UTC
From: miskinis@aidev.enet.dec.com
Message-ID: <5133@ryn.mro4.dec.com>
Source record: 47932

Has anyone come up with a mechanism to record MIDI data at high speeds, and allow mouse movement/operation? I'm getting all the data, and timestamping it OK, but I will always get corrupted data when I start moving the mouse. I bring this up again and again, in the hope that someone new to the conference will see it and post a routine that solves this problem. I know it can be done, as the best sequencers for the ST appear to do it perfectly...

I use a drum machine, at maximum tempo, playing a loop of a complex pattern for testing, and move the mouse in slow circles. It seems to generate a MIDI overrun about every ten seconds or so, on an intermittent basis.

A shot in the dark from someone who want's to provide the world's musicians with a software system that make the Atari ST shine,

John

```

I thought everyone on this net are clever enough what to do if the printer was off and the monitor was completely dead. Yes, MIDI OUT port can be used.

People say when their monitor breaks down, either the picture will be distorted or the picture won't come at all. Gathering from what I have heard, the power supply and logic board die earlier than the Cathode Ray Tube, so the sound won't come out in this case. The printers are normally very robust (having lived in Enland long, I know that is not the case there), so if the printers do not run it is the CPU that would be suspected, not the monitor.

> this problem. I know it can be done, as the best sequencers for the ST
> appear to do it perfectly...

I don't know about posting any code...
Your problem is simply that moving the mouse generates _lots_ of data.

There are several ways of getting around this. One, tell the IKBD to shut up about the mouse, and then, when you know you have the time, ask it for a position update. You can also use IKBD fn $13 to shut up the keyboard for a short period of time, and it will attempt to buffer mouse movement...

-all this, of course, means that you have to do your own mouse handling. No more Gem. This may be OK. Another alternative is to rewrite the mouse interrupt handler, assuming you can find it, and decipher what it is doing. Note that this is a _real_bad_idea_ and should only be considered in utter desperation.

You don't need no disk formatters. Just format using GEM Desktop, and
change the first 3 bytes of sector 0 to EB 34 90 (hex) with a sector
editor. Works like a charm. Just don't put any '+' signs in your TOS
filenames...

I tried this once, but failed big way. Turning the IKBD off for a moment
didn't seem to turn off keyboard interrupts coming in. Turning it on again
didn't always result in proper mouse handling afterwards. I also tried
shutting off the keyboard interrupt via Jdisint(), but this led to even
more trouble. I am _very_ interested in any hint to this problem.

From: ralph@laas.fr
Message-ID: <RALPH.91Jun6153116@orion.laas.fr>
Source record: 47885

1) As I understand the Mega STe has room for a co-processor chip.
Does the chip come installed or is it an option? I suppose that it is
a 68881, right? Is it also at 16 MHz? Do there exist compilers which
generate code for it?

2) The MegaSTe comes normally with a 48 Mb SCSI disk installed. Can
someone send me the specifications of this disk? Average seek time,
etc. ?

Thanks folks,

When I bought my ST (in '87), I was disappointed by the quality of the color
monitor I received (I'd seen a friend's ST & color monitor -- one of the
original ones that was nice and crisp). Soon thereafter, I took the back off
of the monitor & proceeded to adjust every pot in sight, hoping that I could
get it to look like my friend's. Needless to say, I got everything all out of
whack... I managed to get it looking decent again, but have always wondered
if it's adjusted the way it should be. Can anyone offer suggestions on how
to check my adjustments -- rules of thumb, and the like? Perhaps a color bar
program... That sort of thing...

Thanks in advance...

Eric, I've built a cartridge port RAM disk. It's about par with
a fast hard drive when it comes to speed. You are welcome to my schematics
if you want them. I have software too.
As far as a SCSI ram drive, I have seen an 80MB drive. I can't
remember the manufacturer, but I remember that it was very expensive, as
in more than $2K.
If you decide to go the RS-232 route, I'd be interested in what
you have.

Let me just say that IT CAN be done. Me and a friend have written code to do exactly what you ask for. There is only one problem ... the code is well ... proprietary. One hint though: Yes, you must write your own mouse AND MIDI interrupt handler AND you have no choice about the language, it must be assembler. Another hint: the desktop moves the mouse every two pixels not every one pixel.

Oh yeah, when I say the code was proprietary that means it was done on a contract basis and we don't own the source.

Nick.

Well, the reason I wanted to go with SIMMs was that the 256K ones
are getting to be next to (if not) free, and the 1 Meg ones are going to
get to be that way as 4 Meg SIMMs fall even more in price. Yes, SIPPs
would be a *lot* cheaper to mount than SIMMs, but I doubt they are as
easy to find/cheap as used SIMMs. Besides, I *already* have 4 Mb. worth
of 256K SIMMs just waiting to find a home...

This sounds to me like a project eminently worth doing, if I can get
some good books to help my knowledge of digital electronics.

It seems to me that I am not the only one who is waiting for this
answer. I have seen such a posting a few times.
I think the only remedy to solve the problem is to rewrite the
mouse handling routine, so that it works a lot faster.
Unfortunately, I have no information of what the mouse handling
routine must do, so that I can't rewrite this routine.

John, I hope that you are using an interrupt routine for your
music program, and that it's written in assembly. When it's
not written in assembly, you must try it, it gives less more
MIDI overruns. Also, the shorter the interrupt routine to
handle the midi input, the less errors. As written in
several atari docs, your interrupt routine must take
less than 1 mS. I hope that someone out there has written a
midi routine that works with the mouse. Hope to hear from it.

Geert.

2615. Review of LHARC Test Archive Function

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-07 10:03:59 UTC
From: ralph@laas.fr
Message-ID: <RALPH.91Jun7120359@orion.laas.fr>
Source record: 47887
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

Disclaimer: Errors may have been made in the following discussion. Please excuse me for such. The following says absolutely *nothing* about the capacity of the programs to extract or create LHARC archive files.

I collected as many versions of lharc as I could find on the net. I tested them on orbit.lzh (at atari.archive) as well as a lharcsrc.lzh that Bammi had passed to me. Orbit.lzh starts with an uncompressed member file hiscore.orb, which seems to be troublesome. I would very much appreciate to hear if others have succeeded testing these files where I have failed!

The testing was conducted on a Mega 4 ST under TOS 1.2 with a 1 Mb RAM disk. The *.lzh files were on the RAM disk and the test was performed under Gulam with the archive programs under test on drive A:\

Name & Version	Author	Result	Comments
Lharc 0.40 beta	Jon Webb	21 CRC Errors(1)	Needs *.* file spec.
Lharc (Unix)1.02	B. Shroka	2 Bombs(2)/OK	
Lharc 1.13b	Thomas Questar	No File Found	
Lharc 1.1308	"	"	"
Lharc 1.1309	"	"	"
Lharc 1.1318	"	22 CRC not supp.	Needs -u option(3)
Lzh11319.ttp	"	22 CRC not supp.	Needs -u option(3)
Lhxarc 1.01	Jon Soerensen	22 CRC Errors	
Lha.ttp 1.21	Roger Burrows	OK	
Fastlzh.ttp 2.8	Gary Burke	OK	
unlzh.prg 1.1	John Harris	Fails Uncompressed/OK(4)	
unlzh.prg 1.4	"	Bad CRC Uncomp./OK(4)	
unlzh.prp 1.72	"	OK	

(1) When only 1 result is given it applies to both orbit.lzh and lharcsrc.lzh.
(2) This version does not appreciate uncompressed members in an archive. It is the only one based on PC version 1.13c!
(3) Otherwise, "No File Found."
(4) Test listing truncates long file names. Both these versions used to abort for me when I had TOS 1.0 on a 1040 ST!

I hope that these results might be of use to all.

From: oostrom@cs.vu.nl
Message-ID: <10170@star.cs.vu.nl>
Source record: 47797

I have a Mega ST4 (Tos 1.4 UK) with an internal ICD micro ST host
adapter and (brand new, empty) 80 meg seagate (1096N??) drive set to SCSI
device #0. Now I want to add an SH205 (with data on it in a Mega box)
to this configuration. The device drivers I have are the one from ICD
and some archaic version of atari's device driver.
Is it possible to use these harddisks at the same time?
What software is needed?

(I would prefer a solution in which I don't have to open my
computer to alter the ID of the internal drive.)

>> * support for different sized SIMMs (256K, 1Meg, 4Meg)

I don't know how they've done it, but ATARI has a 26Meg extension
for the TT. If that one's a (relatively :) cheap solution, it would
be worth using the IMM.

When I was visiting the US in februari I saw an advertisement in some computer journal (maybe the computer buyer) in which a box was offered that acted to the outside as a SCSI device, but the drive was some cards with standard SIMMs. One could plug in a few hundred megabytes when working with 16 Mbytes SIMs. It wasn't very cheap though. The question I have with respect to the Atari is whether it would be needed to write an entirely different driver, because I remember seeing delayloops in one of the older versions of AHDI. Maybe I am mistaken here.
For those interested to look up the add: I only looked in one of these telephonebook like buyers guides of feb and the MacUser of feb and march. Maybe other people have seen these adds.

>Anyone out there? Tnx!

While we haven't actually done this yet, here are a few thoughts on
this problem.
There is 1/3ms between midi bytes, so there is definately room to
handle the mouse if you write your code tightly. Something similar to
this should work.

mouse_handler:

tas flag for mouse processing.

if not processing:
drop ipl to 5
continue processing
check buffer flag for more bytes
rte
if already processing: * hints supplied elsewhere suggest
move new packet to buffer * that you might want code in the buffer
set buffer flag * stuffer which adds every other byte
rte * to the existing offset in order to
* keep the number of queued packets down
* to some reasonable level.

I'm sure in practice, there will be numerous complications to the above
which would need to be worked out.

Can someone mail me the dos and don'ts of using routines that run every vertical blank? If the Abacus ST Internals is accurate in this case, I think I know how to install a routine. However, I'd like to know if it is ok to call an XBIOS routine during that time, what the maximum length a routine should be and so on...

(also, is it correct to add your routine to the VBL queue by altering the system variables? Their locations do not (and will not) change between versions of TOS?)

thanks...

john

I don't think you will find that you can daisy chain a drive when
using the ICD micro host adapter, as this adapter has no daisy chain output.

ICD do state that the only way is with some form of parrallel connection
of Ataries acsi standard.
Iam not to sure what they ment by this..

longj@lonex.radc.af.mil (Jeffrey K. Long) has 4 questions about FSM GDOS:

No, FSM GDOS has not been released yet. Atari is saying 6 weeks, but they have been saying this for quite some time now.

Yes, the newest beta versions that we have, do include drivers for the HP laser printers.

No, Goldleaf can not ship FSM until it is released by Atari. But owners of Wordflair II will be the fist ones to hear about the upgrade and will be able to purchase it through Goldleaf.

Someone on GEnie was looking at translating the docs, but when
they discovered the assembler had no support for macros, they gave up
on the translation. Has macro support been added? If not, what use
is the assembler except for very small projects.
Check out Devpac2, as it is very good, and the Michtron version is
sell for <50$.

Hi Vincent,
What you want to do is possible, but I doubt that you will like
the answer. The ICD Micro adapter (both the AdSCSI Micro and the Advantage@<
Micro) actually change the DMA mode when they are installed; non-ICD host
adapters are not compatible with this new mode for the ICD Micro adapters. Now
the ICD Advantage and AdSCSI have what is called a "dual-mode DMA"; it supports
and converts between the standard DMA mode common between most Atari and Atari
3rd-party host adapters, and the mode supported by ICD's Micro adapters. Have
I lost you yet?! =^)
It really is not as complicated as I make it sound. You will just have
to put an ICD AdSCSI between the external DMA port (on your Mega), and your
SH205. The ID number on your internal drive (inside your Mega) can stil
remain the same, you can still use ICD's software. Good luck and take care,
bye.....................

Luis

I am trying to attach a Mac external SCSI drive (Quantum 105S) to the SCSI port on the back of my Supra 30MB Atari Hard Disk. I'm using the 1988 Supra Software and Host Adapter and it doesn't have the format parameters to handle a Quantum 105S. Also, when I plug up the disk to the external SCSI port, the Quantum 105S is online but the system never recognizes its presence as device 1, LUN:0. I've swapped the 105 and the 30's mechs and the 105 functions fine, but it seems that even after removing the SCSI terminator on the 105, both drives are not working in conjunction. Does anyone know if the Supra Host Adapter of that era can handle the Quantum? Also, if I get an ICD Host Adapter, does that end all of my problems? And finally, a friend told me that I should use Atari's HDX Formatter for my extended partitions because it is the only one supported. Is there some incompatibility between Atari's extended partitions, Supra's and ICD's?

2631. Can I get ML on the ST?

2632. What to do with an old 520?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-10 09:57:15 UTC
From: exspes@gdr.bath.ac.uk
Message-ID: <1991Jun10.095715.2557@gdr.bath.ac.uk>
Source record: 47808

After ages of thinking about upgrading the ROMs and expanding the memory of my old 520ST (one of the originals, no modulator or builtin floppy, external power supply) I stumbled across a friend selling a used 1040STF, system unit only, so I bought that instead. This means I've got a 520 going spare. No monitor, and ancient ROMs, so it's probably not worth selling. Works, so I hate to throw it out. Occurred to me that I could hack it about a bit instead. Question is, what to do with it?

Ideas which have occurred to me are to turn it into an external RAMdisk, to turn it into a super-intelligent printer buffer, or to make it into an external disk cache for my floppy drives. Or, maybe, some configureable combination of the above. I've got a couple of spare floppy mechs, so it could conceivably be used to support a second pair of drives. All assuming that I work out a sensible way to interconnect the two STs, and write the required drivers for both ends.

Anyone else found themself in this situation? Any hints, or ideas that I've missed? Owing to the amount of peripheral stuff I've got plugged in, would be preferable if they spoke to each other through either the DMA or the MIDI ports.

2633. STe peripheral questions

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-10 13:26:57 UTC
From: sgc@robots.oxford.ac.uk
Message-ID: <1837@culhua.prg.ox.ac.uk>
Source record: 47809

I'm posting this message for someone without net-access.

PLEASE DIRECT ALL REPLIES TO THE ADDRESS AT THE END OF THE MESSAGE

Included message begins:

Has anyone connected a PC VGA monitor to the ST? and is it possible?
I am considering buying a monitor, ideally to work with the AT-Once PC board. If I get a colour VGA type PC monitor, could I use it for colour and mono modes on the ST, or am I limited to one or the other. Does a colour multi-scan overcome this?
Also, does anyone know of a cheap and easy way (preferible no soldering) of connecting a high dencity drive to the ST. I have an STE with a 720K drive and ideally would like a HD drive as drive B. I can format disks on my friends PC to 1.44mb, will they work on the STE if I get a PC HD drive, or do I need to alter the controller chip or something?
A few months ago (april I think), Atari ST user, had an article on a new TOS version from a group of hackers in germany, which was going to be a commercial product. Does anyone know where I can get these new TOS roms? They make GEM much faster, and fix alot of bugs. The STE has the TOS roms on sockets, so I think its just a matter of heaving them out and putting the new one in right? Oh, does the product (KAOS TOS I think it was called) work on the STE with blitter?
One last thing on speeding up the STE, does anyone have any programs like Turbo ST, which are PD/Shareware which speed up the STE. I've already got QuickST, but that doesn't work in low res, and it now where near as good as Turbo ST. Turbo ST causes errors where used with the At-Once baord with my hard drive, and doesn't speed it up anyway. Has FATSPEED.PRG been converted to run on an STE now or not?
Help on any of the above topics appreciated - Thanks..... Shane.

2634. Z-RAM made drive go nuts! WHY!!??

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-10 16:08:19 UTC
From: d90-ngp@sm.luth.se
Message-ID: <1674@tau.sm.luth.se>
Source record: 47819
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have upgraded my 1040 STFM to 4 megabytes with Z-RAM. My ST was one of those with soldered MMU-chip, so I let a proffessional do it for me. When I got my ST back I ran the test program. Geee, four megabytes and no complaints! I started to install Neodesk 3, reads files from one disk and started writing on another. Then suddenly the drive starts making noise. It sounds as if the drives' motor tries to move the head right through the side of the machine. Two dialog boxes explains that the drive does not answer and that the disk is full, although it has 800 kilobytes free!!! A couple of minutes later I conclude that MY DRIVE READS AND FORMATS DISKS IN ALL POSSIBLE COMBINATIONS OF SECTORS AND TRACKS, TWISTED AND NOT TWISTED, FROM GEM, FROM NEODESK 2.05 AND FROM ALL PROGAMS THAT I HAVE BUT IT CANNOT WRITE MORE THAN A COUPLE OF KILOBYTES ON ANY DISK!!!

Now I am in desperate need of HELP!!! The proffessional will do his best to fix it, but it would probably go much faster if anyone have had this problem before and can give me any clue where to start dig. You cannot be to detailed.

DETAILED DESCRIPTION OF A FEW MINUTES EXPERIMENTING
==========
Equipment: 1040 STFM, monochrome monitor, Z-RAM and nothing more!

Inside Neodesk 2.05:
Trying to write to an empty disk formated before memory upgrade.
Drive writes some 10 K, makes noise, dialog boxes sais: Drive not responding.
Disk full.
I cancel writing, "Show info..." sais more than 800 K free.

Same test and same result again a couple of times.
Formats disk in different ways, same test, same result.
Try to load First Word +, Neodesk responds:

An address error has occured (3 bombs).

System register:

d0: 00000800 a0: 000030C2
d1: FFFF0F0F a1: 00008092
d2: 00000027 a2: 00000000

ssp: 00001592
usp: 00060A40

instr: 3D6D
sr: 2300={t:0 s:1 interrupt: 011 x:0 n:0 z:0 v:0 c:0}
pc: 00FC60EA

I pressed return, a fourth bomb showed up, all went black and the computer rebooted.
I started Neodesk 2.05 again and then loaded 1st Word +, no problems!
Loaded a rather large document, changed to empty disk and tried to save.
Disk wrote some 10 seconds, then made that uggly noise again followed by dialog boxes telling drive don't answer and (the empty) disk full.
I cancelled. Drive made noise, same boxes. Cancelled again etc.

I reset the computer, made the 1st Word + test again from GEM, computer loads program and behaves as before.

Loaded Calamus (from Neodesk), played around a little. Rubberband boxes sometimes leave sides of the box unerased when changing size, in a way I never have seen before. "Show statistics" tell me that I have 3.3 meg free.
Suddenly... 2 bombs! Crash is so hard that even Neodesk got stuck (never happened before).

I GIVE UP.

2636. 2nd drive in Megafile 30?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-10 23:21:11 UTC
From: michael@gem.stack.urc.tue.nl
Message-ID: <646@rc6.urc.tue.nl>
Source record: 47764

```
main()
{
printf("Hello world!\n");
}
```

I have a 520ST (expanded to 1024k) with a Megafile 30. I have bought a second hard disk 30Mb rll 3'5 inch. Both drives work fine independantly, I removed the seagate ST-238R and replaced it with the KL320 the drive responded normally and I was able to format partion and use it.

On the main print of the Megafile 30 there is a connecter marked j1. (Ok, there wasn't a connector but I put one there.) It looks the same as j0 (20 pin) which is used for the select of the first drive. I connected a longer cable to j2 (34 pin) and connected this to both drives. I connected the second drive to j1 and booted. The system booted but the second drive wasn't recognized at all, not even by the partitioning software (Atari Advanced Hard Disk Utilities (c) 1989 CA400307-004). So I tried changing the positon of the dip switch marked `x' on the Megafile motherboard with no result. I changed the drive select jumper on the harddisk, but this didn't change anything either. When I switched the drives (the 20 pin cables) the second drived worked and the first one didn't.

If anyone on the net (or not on it for that matter) has suceded in connecting two hard-disks to a Megafile controller. Or if anyone knows what I might be doing wrong please help.

We just got a SNASM unit for cross assembling (IBM host) on the ST.

I was wondering if anyone has used one of these things and can tell me what their long term impressions were.

Also, has anyone figured out the Debugging info that is generated by Lattice 5? I realize that it is probably proprietary so um, I was just going to use it in a simple serial debugging tool I was working on...

Where does one go about getting info (low level hardware info) on the MEGA STE, I am especially interested in the DAC (stereo sound) and the scrolling stuff.

I was wondering if anyone has seen a hardware type of debugger or snapshot utility (along the lines of a SOFTICE or like an ACTION REPLAY cartridge) I would like to examine the computer when it has hung up.

Are there any PD linkers out there?

Thanks for any info you can supply....

>some incompatibility between Atari's extended partitions, Supra's and ICD's?

Hi Charles,
As soon as you can, call Quantam's Technical Support and ask
them for the format parameters for the 105S; and while you have them on the
telephone, ask them to send you a technical reference manual for the 105S
(Supra's software will let you enter the parameters manually if you know
them). Remove the terminator resistor pack from the first drive in the DMA
chain (the Supra's drive) only; leave the terminator resistor pack in the last
drive of the chain. Set the Supra as device #0; then the Quantam as device
#1, 2 or 4 or any device # that the Supra software will recognize the
Quantam. Depending on the mechanism that the Supra is using, you may have to
switch the device numbers around.
Now about extended partitions under TOS. As far as I know (and I could
be wrong, somebody please correct me if I am), BGM (or extended TOS) partitions
are the same regardless whether it's Atari's, ICD's or Supra's; at least I have
had no problems with the three (and I use all three of them). If you do want
to use BGM partitions though, make sure that you are using at least TOS 1.04
(1.4) or higher. So long as you are going to use Supra's software; I would
also recommend using PinHead and Diamond Cache. Take care, bye.....

Luis

2639. Re: 1.44 MB project

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-11 10:36:51 UTC
From: ytsuji@wucc.waseda.ac.jp
Message-ID: <5827@wucc.waseda.ac.jp>
Source record: 47824

I posted an appeal for beta testers of a 1.44 MB drive hack six weeks ago and have received 23 responses. I admit the instructions were not intelligible to people who had never used soldering irons, but to be honest, I had expected at least one person would succeed to build a fine adaptor or at least one person would be asking me to lend the adaptor. I shouldn't have been surprised to realise how really few people are seriously committed to ATARI ST. After all, we haven't had real applications other than music and printing.

No more of gripes, but just let me issue a final appeal. Is there anyone out there (developers are most welcome) who would like to build a 1.44 MB floppy drive adaptor? Mine works perfectly (now designed to be plugged into the socket of WD1772). It works perfectly (without any software tuning at all) with TOS and Minix with standard high density drives (it can boot from a high density floppy too).

I do not like to send documents to info-leaches, but if you are willing to to buy a high density drive (and a WD1772-0202) I would very much like to share the pleasure of using the industry standard floppy disks even if your technical background is poor.

Incidentally, the minimum model requires soldering 3 14-pin chips and optimum model 6 chips (about 84 soldering points). The minimum model preserves the original WD1772 and has 6 jumper lines while the optimum model has its own Wd1772 socket but has only one jumper line.

Write to me if you are reading my article the first time and interested.

Tsuji
ytsuji@cfi.waseda.ac.jp

P.S.
I don't write to people who don't write to me.

The problem with your appeal is that we all already have HD disks connected
to our STs 8-) - at least in Germany. I was one of the developpers of this
hack; our article appeared in 'ST-Computer' 1/90. Commercial HD disk
adapters are available at every corner, and the principles used are
published. This is probably why you got such a weak response.

Before calling BIOS or XBIOS routines from interrupts, you should
use BIOS_ON, afterwards BIOS_OFF, which are macros used to manipulate
the bios register stack.

```
#define SAVPTR (*(char **)0x4a2)
#define BIOS_ON (SAVPTR += 46)
#define BIOS_OFF (SAVPTR -= 46)
```

>(also, is it correct to add your routine to the VBL queue by altering
>the system variables? Their locations do not (and will not) change
>between versions of TOS?)

Yes, it's ok.

I didn't know of your hack, I am very sorry. What I have known is a product
known as HD-Module from ATARI-WORKSHOP in Windsor (England), which I assume
comes from Compu-ware (I see German names like Herrman on the manual). It
is the size of a WD1772 so that it can be soldered on the Wd1772 easily.

If that was ever as good as it claims, I hadn't had any reason to make my
own. A couple of fatal defects I couldn't stand:
(1) No way of connecting two HD drives. (the interface is default GND!)
(2) Have to set the step rate. Or leave the step rate 6 ms for 2DD mode.
I will have to recompile or do something for all the software that
supposes 3 ms the default speed (e.g. Minix). I cannot forget I
left an HD floppy in the slot when I boot.
(3) Non-standard formatting program (They think TOS's formatting
program is good enough and use bios calls to physically format
18 sectors per track.)
(4) the way LOW_DENSITY signal was created with the help of a transistor
couldn't please me.

The fact there are either uninterested people or people satisfied with the German product compels me to cancel my posting in a day or two. If Herr Brod and other Germans could fill the gap and advise people to contact the company that sell the adaptor, I think I shouldn't stand in their way.

Tsuji

2646. keyboard pin-outs wanted.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-11 23:05:51 UTC

Source record: 47829

Many people have files from their Atari 8bit days that they would like to
bring to a msdos disks for their ST.

Solution: At msdos.archive.umich.edu(141.211.165.34),
get /msdos/disk/atario.arc
This is a program (and Pascal Sources!) that allows
an msdos machine to read Atari 8bit double density disks.
It can work in either binary or text modes.

Aside: I actually took the sources and made it filter files from Atariwriter
format to Wordperfect 4.2 format!

2648. Ste DMA chip replacement

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-12 07:55:58 UTC
From: csual@warwick.ac.uk
Message-ID: <HD8_RY$@warwick.ac.uk>
Source record: 47828

I know that early STe's were affected by a problem in the DMA chip which corrupted some hard disks, and that Atari would fix the problem for free only if you had a problem with one of their Megafile HD's.
I have an early STe and am thinking of buying a HD soon, but I don't want to wait until the think screws up before I do anything. How do I tell if I need a new chip, and if so, what do I have to do if I want it replaced? I don't expect to get it for free (although I think I should as it was a design fault), but I just haven't heard anything about this. Could Allan Pratt give me the official Atari line on this one? Pretty please?
Anybody else got any news on this? E-mail preferred on either:

jas@uk.ac.warwick.cs
or
csual@uk.ac.warwick.cu

Ta very much,
Jas.

You need a copy of Magic Shadow Archiver (MSA), which compresses an entire disk into a (big) file, including formatting info. It is on atari.archive, probably under the name shadow.arc (in the archiver directory).

2653. Z-RAM made my drive go nuts! WHY!!?? CORRECTION.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-12 13:38:02 UTC
From: d90-ngp@sm.luth.se
Message-ID: <1676@tau.sm.luth.se>
Source record: 47837
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have upgraded my 1040 STFM to 4 megabytes with Z-RAM. My ST was one of those with soldered MMU-chip, so I let a proffessional do it for me. When I got my ST back I ran the test program. Geee, four megabytes and no complaints! I started to install Neodesk 3, reads files from one disk and started writing on another. Then suddenly the drive starts making noise. It sounds as if the drives' motor tries to move the head right through the side of the machine. Two dialog boxes explains that the drive does not answer and that the disk is full, although it has 800 kilobytes free!!! A couple of minutes later I conclude that MY DRIVE READS AND FORMATS DISKS IN ALL POSSIBLE COMBINATIONS OF SECTORS AND TRACKS, TWISTED AND NOT TWISTED, FROM GEM, FROM NEODESK 2.05 AND FROM ALL PROGAMS THAT I HAVE BUT IT CANNOT WRITE MORE THAN A COUPLE OF KILOBYTES ON ANY DISK!!!

Now I am in desperate need of HELP!!! The proffessional will do his best to fix it, but it would probably go much faster if anyone have had this problem before and can give me any clue where to start dig. You cannot be to detailed.

DETAILED DESCRIPTION OF A FEW MINUTES EXPERIMENTING
==========
Equipment: 1040 STFM, monochrome monitor, Z-RAM and nothing more!

Inside Neodesk 2.05:
Trying to write to an empty disk formated before memory upgrade.
Drive writes some 10 K, makes noise, dialog boxes sais: Drive not responding.
Disk full.
I cancel writing, "Show info..." sais more than 800 K free.

Same test and same result again a couple of times.
Formats disk in different ways, same test, same result.
Try to load First Word +, Neodesk responds:

An address error has occured (3 bombs).

System register:

d0: 00000800 a0: 000030C2
d1: FFFF0F0F a1: 00008092
d2: 00000027 a2: 00000000
d3: 00000000 a3: 0005DF08
d4: 00000000 a4: 0000313A
d5: 00000000 a5: EB7E4A11
d6: 00000006 a6: 000015E2
d7: 00000006 a7: 00001592

ssp: 00001592
usp: 00060A40

instr: 3D6D
sr: 2300={t:0 s:1 interrupt: 011 x:0 n:0 z:0 v:0 c:0}
pc: 00FC60EA

I pressed return, a fourth bomb showed up, all went black and the computer rebooted.
I started Neodesk 2.05 again and then loaded 1st Word +, no problems!
Loaded a rather large document, changed to empty disk and tried to save.
Disk wrote some 10 seconds, then made that uggly noise again followed by dialog boxes telling drive don't answer and (the empty) disk full.
I cancelled. Drive made noise, same boxes. Cancelled again etc.

I reset the computer, made the 1st Word + test again from GEM, computer loads program and behaves as before.

Loaded Calamus (from Neodesk), played around a little. Rubberband boxes sometimes leave sides of the box unerased when changing size, in a way I never have seen before. "Show statistics" tell me that I have 3.3 meg free.
Suddenly... 2 bombs! Crash is so hard that even Neodesk got stuck (never happened before).

I GIVE UP.

UPDATE: A few hours later I made another test: I tried copying files to a ram-disk (in GEM) and my ST bombed again. I restarted with the on/off button and tried again a couple of times. Each time two files were copied and then either one or two bombs showed up.

CORRECTION: Sorry, in the last sentence I mean ...either two or three bombs showed up.

In the latest ST Format and I quote:

"Bob Gleadow, Managing Director of Atari UK, is keen to clear the air about STE DMA problems. As FORMAT reported in issue 16, a faulty DMA chip in some STEs could result in hard drive data becoming corrupted after just a few hours' use. Gleadow told FORMAT that if you've got a problem with your STE, and you can prove it's a legitimate DMA problem, then Atari will deal with it free of charge. If you feel your STE is one of the "small" batch of machines that has a duff DMA chip, then phone Atari on 0753 33344 for the technical department. Oh, and tell 'em ST FORMAT sent you."

>

Down these same lines, does anyone know what the OS entries in the VB queue are used for (I know there are many different versions of TOS, but their function may be similar). If I make my VBI the only entry, then I can get 130,000 cycles of processing time during each VBI. Of course using this much processor time during each interrupt means that your main CPU process is running with very little processor time. Somewhere during that 130k cycles the next screen refresh is already taking place, so don't count on the screen refresh to wait until your VBI is over.

Another question. From my experimentations, I have found that it is possible to have very long VBI interrupts (perhaps a 2 second interrupt). Think of this as a one time interrupt. Now during this way-long interrupt, is it true that no more VBIs are processed until it is over? Also, is the main process halted completely while it is running?

If anyone is interested, I have a tiny assembly routine that will install a VBI, and another to restore the old entries. If a few people are interested I will post it (very short, but I don't have it with me at the moment).

Later,

Erik R Johnson

The source code for the MiNT library is also available (by FTP from
atari.archive, for example). Porting this to Sozobon is certainly possible,
although potentially difficult. Some of the functions (e.g. in the stdio
library) originally came from dLibs anyways, although Jwahar Bammi and
I (and other people as well) have hacked on them quite a bit.

>> ytsuji@wucc.waseda.ac.jp (Y.Tsuji) writes:
>> >I posted an appeal for beta testers of a 1.44 MB drive hack six weeks
>> >ago and have received 23 responses.

I responded back then and have exchanged ideas with Y.Tsuji. His suggestion
for eliminating the need for changing the step rates is simple yet effective.
I am surprised that for nearly 2 years (or longer?), people have struggled
with fixing software drivers or they accept using a slow step rate for DD disks.
There are various other hints and tips which don't seem to be mentioned in the
ST-Computer 1/90 article.

>> The problem with your appeal is that we all already have HD disks connected
>> to our STs 8-) - at least in Germany. I was one of the developpers of this
>> hack; our article appeared in 'ST-Computer' 1/90. Commercial HD disk
>> adapters are available at every corner, and the principles used are
>> published. This is probably why you got such a weak response.

Germany is the most active area for Atari computers, but there are others.
Not everyone can read German, and many users never see the magazines.
The project in the magazine article seems to handle only one HD floppy drive.
Obviously it works, but it didn't suit my purposes. I had a look at an HD
adapter module from 'Hard and Soft' in Germany. It also could only handle one
HD drive, but at least it generates the 16 MHz clock signal on board and
divides it to 8 MHz for DD disks. I think this was a different product from
the CompuWare HD-Modul. It doesn't buffer the side-select signal and there is
no provision for fixing the media-change problem on those floppy drives which
are smart enough to keep track of disk changes.

>What I have known is a product known as HD-Module [...]
>If that was ever as good as it claims, I hadn't had any reason to make my own.

It was the same for me. I have just finished building my own circuit design
on wirewrap holeboard (the first attempt was on stripboard which caused too
much interference in HD-mode).
Public thanks to Y.Tsuji for the correct handling of steprates in hardware,
and other invaluable help.

It is only right that manufacturers and users of commercial hardware, and
hobbyists / hardware hackers are aware of the limitations (some of them serious)
in the equipment. I'm glad I didn't have to buy a WD1772 accelerator module,
only to find I couldn't use it anyway without redesigning from scratch.
I'm sure others have been less fortunate and have to put up with what they
bought because they had incomplete information when they bought it.

Anyone who wants to build an HD floppy control board for their ST should definitely benefit from reading the 1.44 MB project docs by Y.Tsuji.

You don't have to be sorry. It's just that you wondered why interest
was so low, and I tried to explain meaning to be helpful, nothing else.

>If that was ever as good as it claims, I hadn't had any reason to make my
>own. A couple of fatal defects I couldn't stand:

> left an HD floppy in the slot when I boot.

This leads me to think that this is a direct copy of our solution presented
in 1990 which also needed a separate step rate program.

> (3) Non-standard formatting program (They think TOS's formatting
> program is good enough and use bios calls to physically format
> 18 sectors per track.)

What's so bad about Flopfmt()? I really don't understand the problem
here.

> (4) the way LOW_DENSITY signal was created with the help of a transistor
> couldn't please me.

Our solution didn't use transistors for this purpose.

>The fact there are either uninterested people or people satisfied with the
>German product compels me to cancel my posting in a day or two. If Herr Brod
>and other Germans could fill the gap and advise people to contact the
>company that sell the adaptor, I think I shouldn't stand in their way.

You don't have to cancel it just because there are other solutions for it.
The fact that you have attracted about 20 people willing to build your
HD circuit means that there is interest, albeit not as much as you'd like
to have.

In Germany, there are at least 10 commercial solutions for this purpose.
One of the best is sold by OverScan GbR in Berlin.

I get the impression that David Parsons (orc) has already done this in
conjunction with his work on Bauble UUCP (see comp.sources.atari.st).
Maybe he can be persuaded to release his libraries.

On a related note, is there any further info on a new release of
Sozobon C?

And does *anybody* have the full set of sources and examples for GEMFAST
version 1.5?

Yeah, that has certain drawbacks, particularly when working with limited physical desktop space... But now I've got it all hidden inside a tower case, standing next to the desk...

>> * Serial interface, possibly with a native CPU. This would definitely
>> be slow, even at 19200, but would be supremely portable to non-ST
>> systems.

Why bother building a solid-state disk only to slow it down behind a silly
serial interface? Remember 8-bit Ataris? 5-1/4" floppy drives using SIO
at a blazing 19200bps?? If you want to drop to that speed, just get some
Old Old Old hard drives, you don't need to waste bucks on DRAMs...

You could consider the parallel port; it's bidirectional, and most new
PC clones also have bidirectional ports now. (If portability is a big
issue...) Not sure what the top speed is for that though, I think it's only
around 1000cps, which is only slightly faster than a 9600bps serial port...

>> * SCSI interface, possibly with a native CPU. I imagine that this
>> would be rather expensive to build, due to the cost of SCSI chipsets and
>> an ACSI->SCSI converter board. It would, however, be useful on non-ST
>> systems. Throughput would probably be not bad.
>Native CPU more or less essential, (68000 series (eg 010, 070) weould be
>good)
>The NCR 5380 - SCSI chip, is not very expensive. Easy to talk to as well.

Wanna be even *more* clever... Use SRAM, as suggested, mounted on a removable
carrier. Battery on-board the cartridge, of course. That would be really
slick...

I saw a mention of a program that allows you to use 8bit drives on your ST.
Appearantly you have to make a cable that connects the SIO port to your
parallel port. The public domain watch I read warned that they weren't
very useful since you can't put much on them :)
I doubt that you can read normally formatted atari 8bit disks.

I DO have 3 8bit drives around, and would like to play with that idea for
the novelty.

Hmm, with the new bigger then HD floppies comming out why dont we just jump to those? ;-)

I am definetly interested in having a HD floppy in my machine...
I have a '386 sitting here with a HD 3.5" disk in it and it would be great to only use one type of diskette.

2677. I/O thru centronics port

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-14 07:30:16 UTC
From: yonder@netcom.COM
Message-ID: <1991Jun14.073016.12294@netcom.COM>
Source record: 47856

Could somebody give me some tips on setting up the
centronics port for I/O.

I have tried (in Sozobon):

Giaccess(data,15+0x80) ;0x80 = bit 7 = write

Then to test to see if this works I try to STROBE using On/Off/Ongibit(5),
in hopes that CHR$(data) will print out on my printer. Doesn't work.

Also when I try reads:

data = Giaccess(0,15)

with nothing connected to the printer port, I get 0 returned. I think I
should get back $FF, what do you think?

Anyways, I just started playing around, but I would like to use the
parrallel port to read and write data (I'm playing around with a
PowerGlove).

I've also tried to use assembly:

lea $ffff8800,a0 ; ff8800 = GI chip address
move.b #7,(a0) ; I want to let the GI chip know I want reg. 7

But the move gives me a bus error. I tried do a Super call first, but
I still get the bus error.

I'll admit that this is the first stuff I've written on my Atari
using these calls. I've got a couple of the Abacus books that I'm
using for reference.

Optimum would be if someone could show me a couple of short examples
for both read and write to the port.

Thanks.................

From: johanh@Sweden.Sun.COM
Message-ID: <23498@sunswe.SE>
Source record: 47866

My setup is: 1040 ST with an ICD host adapter, Adaptec ACB-4000 controller
and a Micropolis disk. I also recently got an Adaptec ACB-3530 (SCSI to
QIC-36 streaming tape controller) and a 60MB tape drive.

Is there any ICD software available that supports a streaming tape
drive like this?

I also have a danish ACSI->SCSI adapter (a university project, I think)
with Turbo-C/assembly source for the board (a basic hard disk driver).
Thus, I am also interested in pointers to driver-source for 60MB tapes.
If there is no software available for the ICD adapter, I will probably
have to write a driver myself.

> carrier. Battery on-board the cartridge, of course. That would be really
> slick...
> --
> -- Howard Chu @ Jet Propulsion Laboratory, Pasadena, CA
> Disclaimer: How would I know, I just got here!

Looking in my Radiospares (yes, we have them here too) catalogue, I find
catalogue number 657-246 : a 512Kx8 battery backed memory card,
physical dimensions 86x54x3.4mm.

Turning to my pricelist, I find the one-off price to be A$1161.80

Immediately I look at the smaller components :)

The 32Kx8 card is still A$252.76.

Somehow I feel I will let someone with some more money than me play with
these.

From: jmack@b11.ingr.com
Message-ID: <1991Jun14.143122.14136@b11.ingr.com>
Source record: 47859

There are two ways, that I am aware of, to connect an Atari 8-bit
drive to the ST. Both methods require a cable connected from the 8-bit
to the ST's printer port. These cables can be purchased from a couple
of places that I can't remember right now. I have several of these things
if anyone is interested in them. (This is NOT an advertisement mind you,
just trying to help out...)
1) Use Darek Mihocka's X-Former software. It is a program you
run that lets you read files (in the 8-bit's format) from
your old drive to your ST.

2) Use SIO-Driver. It is an autofolder program that lets you
add a disk icon to your desktop representing the 8-bit drive
so you can access the 8-bit disk like normal, with the ST's
file system.

In article <A1458312909@thelake.mn.org> steve@thelake.mn.org (Steve Yelvington) writes
(About MiNTable libraries for Sozobon):
|I get the impression that David Parsons (orc) has already done this in
|conjunction with his work on Bauble UUCP (see comp.sources.atari.st).
|Maybe he can be persuaded to release his libraries.

Yes, but there's one *little* *tiny* problem - there is no documentation of
libc - I've been trying to write documentation, but writing documentation for
a library takes the concept of staggeringly dull to a previously unknown and
unimagined level. And they're rather personalized - I've only spent the effort
trying to make the bits I need to use work properly, and the other bits, many
of which I've liberated from dLibs, are just the way they've always been.

I'll be happy to email copies of my libraries and header files to people, but
I get the sneaky suspicion that they are in no way mature enough to feed to
comp.{binaries|sources}

From: rcte2p@menudo.uh.edu
Message-ID: <1991Jun15.003342.28382@menudo.uh.edu>
Source record: 47867

Well, in the past, I have simply glossed over all the plees for information about their mono monitor having the shakes.... I thought, gee, those poor unlucky people. I have had my 520ST (2.5M) and the same mono monitor since 1986 - it can never happen to me...

How wrong I was. But, I do know that this DOES NOT seem to be a problem with the monitor but I could be wrong. I say this because whenever I do a disk access or have a program that uses alot of CPU (like 3-D cad...) the "shaking" of the screen stops... and this is not exactly shaking (it seems to shake when I use Uniterm) because when I am on the desktop, I can see a series of distortions traveling up the screen... I thought it might have been that my st was hot, so I opened it up and none of the chips felt unusually hot... I suspect it has something to do with the video shifter... but I am not sure... Any one want to fill me on how I can isolate the source of the problem and have it repaired?? Maybe now I can get the TT I so dearly want....

Thank you.

When the logic gates are so many, you might wish it to have only 28 pins or
so. But when the total pins of logic chips are less than one PAL or GAL or
whatever, I don't see any merits in using one. People use GALs to prevent
others to copy the hardware.
Talking of GAL/EPROM programmers, I wonder if we have loads of software
in atari.archive.umich.edu (to which I am not admitted) to make use of them.
There are dozens of those programmers around that can be plugged into
our serial ports or parallel ports and translating msdos software shouldn't
be difficult.

2686. 1024-byte floppy sectors?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-15 12:16:16 UTC
From: adamd@rhi.hi.is
Message-ID: <3251@krafla.rhi.hi.is>
Source record: 47870

I have formatted disks with 1024-byte sectors, both by using my own version of the Minix formatting program and with the excellent format option in Knife-ST from Hisoft. Both in TOS (1.2) and in Minix (1.5:4) there are serious problems. TOS cannot read any sectors with this format and displays the data damaged dialog. Minix produces DMA error status 0 at present, but I am working on this with a little help here and there.

1024-byte sectors are very useful on HD floppies because although it is possible to squeeze 22 normal 512-byte sectors onto a track, this is slow and potentially unreliable. 11 sectors of 1024 bytes each fit comfortably on the track though, so 10% more space becomes available in a reliable format.

TOS uses a BPB to handle various media specifications. The floppy driver / filing system must use 1024-byte cluster buffers for the standard format. Why should it not be possible with standard TOS to use 1024-byte clusters of one sector each? What modifications do I need to make to TOS in order to use the larger sectors with it?

Any thoughts / suggestions welcome.

From: ytsuji@wucc.waseda.ac.jp
Message-ID: <5853@wucc.waseda.ac.jp>
Source record: 47872

Using a 1024-byte-sector format is a waste of time. If you want disk space, why not use cheap hard disks. Hard disks are least expensive storage media now (1.2 giga bytes costs as little as US$2100! And you must have experienced being asked to take charge of obsolete disks from your friends).

I actually have a driver for 1024-byte-sector MSDOS disks, but as it calls ROM routines directly, I cannot post it to the public. I thought Adam could have written the code blind-folded.

>wires from the keyboard to the computer.

Below is the layout for a standard ST keyboard, on Mega-ST's KBDAssy, pin 18
is missing.

(01) ground
(02) (no pin, protection)
(03) J1 R
(04) J1 L
(05) J1 D
(06) MBut R / J1 Fire
(07) J1 U
(08) M Y2 / J0 R
(09) M Y1 / J0 L
(10) M X1 / J0 D
(11) MBut L / J0 Fire
(12) M X2 / J0 U
(13) VCC (+5V)
(14) TxData -> 6850
(15) RxData <- 6850
(16) Reset (not used but working on Mega-ST KBD)
(17) J1 Pin 5
(18) KBDClk 4 Mhz

Hope that helps, Bjoern

btw: The keyboard circuit diagram says something about pin 37 of 6301 chip
being used as a Caps-Lock indicator -> transistor -> led.
Anyone ever got this feature to work ?
I have achieved nothing, so I think it has to be made in IKBD's OS.

Answers via mail, please.

The BIOS in the ST is set up to only read 512 byte sectors, that is
the Big problem.
I did see a program that installed a ACC that would support 512/1024
bytes sectors and you set up different drive id's, this was in the
Package called HyperFormat.

Note: some game programs use the 512/1024 sector format, this is equal
as the 11 sector format, but with out the problem of using 11 sectors.

Source record: 47876

Hi Atari/ICD specialists,

this weekend I got troubles with my harddisk. I have a Quantum harddisk
connected to my ST4 by an ICD controller. I repartioned the disk and now
I cann't access the drive. What happens is the following:
a) when turning on the monitor, the harddisk, and the ST4 (with the ICD
bootfloppy inserted), I get bombs 4 bombs,
b) when turning on monitor, the ST4 , and the harddisk, I get the message
"Daten auf Floopy defekt ?", which means that the ST4 cann't access the
floppy drive.

I'm running TOS 1.4 and the ICD software vers. 5.2 . Any recommendations /
hints to overcome this behavior are welcome.

The SIO-Driver includes a generic '8-bit look-a-like' SIO interface,
so it would be possible to hook anything (except a cassette) to the ST.
Unfortunately, the only driver available (so far) is for the disk drives.

The problem is as follows:
A sector-size of 512 bytes is *hardcoded* in (older) TOS versions !
TOS can recognize other sector-sizes than 512, and reports them right
in the BPB, but internally, the floppy routines, which access the DMA
controller, expect 512 byte per sector.
So, the only solution is another TOS-Patch ...

Hope that helps !

Greetings,

Robert

In fact, the problem is even more complicated than this: The TOS 1.0
floprd and flopwr functions could handle 1024 sector sizes! This,
however, was a side effect of the FDC command used, not a deliberate
design. Due to problems with the old solution, this undocumented features
has been removed.

It's not too hard, however, to write a 1024-bytes-per-sector floppy driver.
Actually, I've seen one some time ago; it had been sent to me for
testing purposes.

>use the larger sectors with it?

>Any thoughts / suggestions welcome.

You are mistaken in your belief that TOS keeps cluster buffers around. It doesn't. It keeps SECTOR buffers around. The floppy BIOS assumes sectors are 512 bytes long. GEMDOS does not, and hard-disk partitions larger than 16MB are implemented using large logical sectors (but not large physical sectors) with appropriate values in the BPB. To use 1K sectors on floppies you would have to replace the floppy BIOS completely, and include in your TSR a routine which replaces GEMDOS's sector buffers with new buffers large enough to handle the largest sector size in your system. This is what the hard disk driver has to do (except that instead of replacing the floppy BIOS it's installing the hard-disk BIOS).

From: nils@ooc.uva.nl
Message-ID: <20806@slice.ooc.uva.nl>
Source record: 47882

Is there any other compagny wich makes acsi to scsi converters
at a lower price as Atari does??
and what do they cost then??
Because if there aren't i'm going to develop my own (private) copy,
'cause the atari prices for loose components are far too high for an ordinary
student who just wants to expand and play arround with his atari.
By the way, wy didn't atari have the decency to put in some buffer chips into their
computer? I am willing to pay the few extra dollars it would have costed me.

nils.

2700. What path was I executed from?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-17 21:54:40 UTC
From: cummins@d.cs.okstate.edu
Message-ID: <1991Jun17.215440.10349@d.cs.okstate.edu>
Source record: 47747

How can my program find the path it was executed from if it's not executed from the current directory?

for example:
A BBS program (C:\bbs\bbs.tos) calls a door program (C:\bbs\doors\door1\door1.tos). I want the door program to be able to find it's related datafiles (located in the same directory as the door1.tos file) w/o resorting to having the user write a text file with the path in it, and putting it in the current directory (such as C:\bbs\door1.pat containing the path where the data files are to be found).

Seems to me this is somewhat like opening a window to a program/.rsc file, then opening a second window, executing the program in the un-topped window by ... holding down the right mouse button and then double clicking. Ordinarily... any support files in the same directory as the program won't be found. What's the proper way to "fix" this. As I would like the Door software to be trivial to install.

It was a 3D view, but of course, the `TOP' drawing windows show a 2D floor plan.

2703. MV16 sound cartridge.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-18 10:20:10 UTC
From: adm2@doc.ic.ac.uk
Message-ID: <1991Jun18.102010.19752@doc.ic.ac.uk>
Source record: 47889
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech
Body handling: HTML body converted to readable text

Hi,

Well about a month ago,I posted a request for information about using the MV16 sound cartridge,what comes with BAT,for playing samples.I receive little response,unfortunately apart from Dave Lockwood .So I imagine,that not many people out there know how to use it,so after some work ,I have finally worked out how to use it .

So what follows is a describtion of how to play samples through the MV16 sound cartridge,which gives 16-channels of mono 8-bit sound!

The first thing that must be understood is that,because the MV16 plugs into the cartridge port then it is not possible to write data directly to it along the data bus.This is due to the MMU or GLUE,which has this area $FA0000 to $FBFFFF marked as read-only.So what is needed is to find the way in which the volume and channel data is passed to the cartridge.

Now as Dave,rightly pointed out,this is simply done by using the address lines. So to send some data to the cartridge port,you simply place the data as the lower 1->15 bits of an address in the range $FA0000 to $FBFFFF and then when you read this address,those lines are setup correctly.

NOTE:- That the cartridge port is Word addressed and so even though the address may be described as bits 0->23,the zero bit is not used in the cartridge port ,so that even addresses are always used! And the higher bit`s describe the cartridge port area of 128k at $FA0000.So this gives us the bits 1->15 thru the cartridge port.

Now all that was needed was to work out which of the bits 1->15 did what,with a MV16 plugged in.To do this,I sat down with my trustly electronics/computer reference books,a ST and a disassembled MV16 and se about some reverse engineering!

And this is what I found.Firstly bits 1->4 ,of the address,denote what channel to use.And secondly the bits 5->12,of the address,denote the volume data to play on that channel.So an addresses bit pattern looks like this:

```
Bit 1 1 1 1 1 1 0 0 0 0 0 0 0 0 0 0
5 4 3 2 1 0 9 8 7 6 5 4 3 2 1 0

$FA # # # D D D D D D D D C C C C #

| | | | | | | |
Higher < N/A > < volume data 8-bits > < channel> Not used
Bits
```

Give
$FA

So to play the data 10101010 on channel 16 (1111) then you only need to use:

MOVE $FA155E,R0 where $FA155E is the hex (111110100001010101011110)
| | | || |
< $FA >

And it`s as easy as that...

So if you`re thinking of producing some sort of sample playing program,
either commercial or PD,please include support for the MV16 sound cartridge!!!

NOTE:- To test if the cartridge is present,play a note of zero volume and if you
can a none zero value back then it's there,I think...

NOTE:- These are only provisional outcomings and are not guaranteed to be
perhaps after the summer,if there are any correction needed then a newer
version will be published... If you wish to upload load this to a archive
or BBs please feel free.

Well, no one seems to have any hi-tech project ideas for my ancient
ST520, but I got a (hopeful) lateral-thinking piece of mail from
someone in Virginia, as follows:

> From: lch3e@edu.Virginia.acc.holmes (Lauren C. Howard)
>
> Hi! You can always donate the poor thing to our school!
> The Einstein School is a small private school where I teach
> computers to children with dyslexia and other learning problems.
>
> We use lots of Atari's, tho we have only 1 ST to date (needless
> to say, it's the most popular machine!). We can always use more!
> For our purposes, they work pretty well with a TV set.

As I told Lauren, I don't think my ST would meet their needs, not least
because it uses 50Hz 240v electricity, and outputs 25 frame/sec
625-line RGB, and contains neither modulator nor disk drive, but the
overall concept is sound.

If you've got an old ST (or other home computer) lying around, you
probably could find some such (semi-)charitable organization near you
who could make very good use of it. Might be worth thinking about.
(If you're in the US, you should even be able to claim a tax deduction
for it.)

>
>Taitt

Hi Henry,
Trying loading one of the mazes for MIDI Maze II, into either a word processor or text editor; it (the .MAZ file) should be just a ASCII text file that you can edit (at least I know this works with the original MIDI Maze).
By the way, keep an eye out for a new program called "MAKAMAZ", it will create, edit and randomly generate .MAZ files for MIDI Maze (probably also MIDI Maze II (both MIDI Maze II's)). You just point the mouse, click... and draw or edit your mazes. It was written by Perry Robins of Moonlite Software. By the way, I've been beta-testing it..... it's almost ready for release; in fact Perry is just finishing up the documentation. Bye.....

I have posted to comp.sys.atari.st -- but just perhaps no one who likes tech is reading that.

My monichrome monitor has gone the way it was designed to go.
It died.

It appears to be the same problem with that resister/capacitor--whatever. However, like a fool, i didn't save the articles on how and what was the best fix for this, since of course, it could never happen to me.

Anyway, while i am in there, I want to do the overscan stuff too.

Please, plsae, either post, email me or tell me where I can find the best directions on how to fix this power supply problem AND do the over scan at the same time.

PS: I just put a "best" power supply in my TOS 1.4 ST cause the old power supplies just died...

DOES ANYONE HAVE THE PATCH TO ALLOW STOS TO WORK WITH TOS 1.4?

Thank you for your bandwidth.

Scott

2711. handling serial io in turbo-c

Newsgroup: comp.sys.atari.st.tech

Message-ID: <00000000.msoysal@mcimail.com>
Source record: 47748
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Hi, I have a problem accesing the serial port with the fgets and fscanf functions.

If I use "aux:" for filename and "r+" option for permissions, I read garbled characters into the buffer, and sometimes it sits there and probably waits for input from serial port, while the data is pouring in.

If I use the predefined stream stdaux, I get a bus error with one of the tries to get something with fgets.

Has anyone done any work with the serial work using Turbo-C ?

Please help

Mustafa

Oh yes, it is. They clearly show at least two facts:

1. You have to fiddle around to get a proper LHarc version.

2. If you pack something with (your version of) LHarc you can't be sure the fellow at the receiving end will be able to unpack it, because he might not have an edequate LHarc.

Your test still leaves open the question if the tested LHarcs are compatible to one or more Unix LHarcs.

I use xlharc that was posted to USENET. It works *very* well, since I test all the archives before bringing them to my Mega 4 ST. I then retest them on my Atari to be sure that all is fine. Its reference is the following:

C-LHarc for
Usage: %s {axevlufdmctp}[qnftv] archive_file [files or directories...]
Version 1.00 (C) 1989-1990 Y.Tagawa, Kai Uwe Rommel

The original Unix lharc had problems for uncompressed file members, a common problem for many of the ST lharc versions that abound. Someone locally patched the initial Unix lharc. Its reference is:

C-LHarc for UNIX Version 1.00 (C) 1989-1990 Y.Tagawa, Kai Uwe Rommel

Unfortunately, they are virtually indistinguishable. Xlharc was posted to the net by B. Davidsen.

Hope that this helps further.

2715. requirements to use VDI

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-19 11:26:06 UTC
From: rosenkra@convex.com
Message-ID: <1991Jun19.112606.20682@convex.com>
Source record: 47752

maybe this is a dumb question but...

is it possible to call VDI routines without writing a full blown GEM application? ideally, i would like to just use something like v_fillarea or somesuch. i realize that i need a device handle, so maybe i need all the other stuff (baggage) too. it would be great to be able to use VDI in .ttp programs. can u open a device without appl_init?

if it is not possible to write a .ttp with VDI (i suppose it is not since the extension tells the OS to either prepare for GEM or don't) then is it possible to read command line args with a GEM program (.prg)? i.e. one doing appl_init, open workstation, etc. if so, how? i use alcyon. my shell is gulam. is it possible with gcc/gemfast/etc?

i'd hate to have to do the fill with line A or directly to the screen. i only need white fills. this makes drawing 3-d xyz datasets (like FFT maps) easy if u draw from back to front. the fill eliminates hidden features of the plot (desirable). i have used this in full GEM progs, but want to use it in .ttp progs where i draw points and lines (with line A). don't beat me up about line A, either. if/when i get a TT, i will switch. as far as i know, line A is the ONLY way to draw lines (other than fixing pixels in Physbase) in a .ttp.

thanx...

>generate code for it?

Both Turbo C and HighSpeed Pascal (Maxon) support the register FPU.
The libarays supplied test if the FPU is in the computer when the first
floating point routine is used or in the startup code, and then uses the
appriate binding...
(emulating or FPU)
I don't think that there is any 'automatic' binding for the TT - yet!

The FPU is allways running 16 MHz...

Klaus.

2718. Fax via modem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-19 13:47:41 UTC
From: ytsuji@wucc.waseda.ac.jp
Message-ID: <5878@wucc.waseda.ac.jp>
Source record: 47757

I am no guru on FAX, but I heard FAX has two modes: one mode sends pictures at 200 dpi and the other sends ASCII codes. Is there public domain software that enables me to send ASCII text from my ST via its modem to a FAX?

Tsuji

2719. 68881 for the 1040

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-19 13:51:54 UTC
From: keiths@cadence.com
Message-ID: <1991Jun19.135154.14769@cadence.com>
Source record: 47758

68881 for the 1040
Status: RO

This describes how you can get a 68881 coprocessor to work with your Atari 1040 or similar.

Basically what you have to do is this; in the following I am using '*' for the inversion of a signal:

AS* is decode from address 0xFFFA40. Only bits A23-A5 are used though. To do this I used two 74HC133 13 I/P nand gates, oring the two outputs together using a 74HC32. Also FC0-FC2 are inputted to the 133's, decode as x01, i.e. do not use FC2 and invert FC1. A single 74HC04 will provide the inverters for the address decode and FC1.

DS* is just the AND of UDS* and LDS*. Other than this, the signals need to be connected just as shown in the 68881 data sheet (you'll need a copy of this, if only for the 68881 pinout). The following shows the connections I used, with MC68000 pins on the left and MC68881 pins on the right.

I soldered 2 26 way IDC cables with connectors right onto the 68000 pins (crude but my 68000 was not socketed, so there wasn't much choice). The use of IDC connectors is recommended as at least you can unplug your atari and use as normal while you're checking your circuit. I built it on a small piece of board with plated-thru holes. If you can make PCB's so much the better, please send me one!

I buffered the clock from the 68000 using a spare AND gate in the 74HC08, since with ~8 inch leads the signal was a bit flaky, giving me errors at first.

Here's the complete schematic, there may be one or two 68000 - > 68881 signals that I have forgotten (I'm working from memory here, I'll check it over the weekend). If I have forgotten anything important I'll remail you.

I tested it with a simple Laser C program linked with the lib881.a library. A test of about 1000 log, exp etc. double precision operations took 7.00s with the standard lib (libc.a) and 0.53s with lib881.a.

Pretty impressive, huh?

2720. File format for Microsoft Write

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-19 13:52:04 UTC
From: podacc@rigel1.concordia.ca
Message-ID: <527@daily-planet.concordia.ca>
Source record: 47755
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I would greatly appreciate it if someone could tell me where I can find
the file format for Microsoft Write for the Atari ST. Also, can someone
tell me if there is a bug with Microsoft Write's print Metafile option?
(I have a utility to convert a Metafile to postscript, but I always get
a metafile corruption error. Unfortunately, I do not know whether it is
a problem with the utility or Write and I do not have another application
that generates metafiles!).
Thank you in advance.

Andrew Francis

>use VDI in .ttp programs. can u open a device without appl_init?

There are good reasons why TTP programs are meant as non-GEM programs.
You shouldn't use VDI or AES calls in a TTP program.

>if it is not possible to write a .ttp with VDI (i suppose it is not
>since the extension tells the OS to either prepare for GEM or don't)
>then is it possible to read command line args with a GEM program (.prg)?
>i.e. one doing appl_init, open workstation, etc. if so, how? i use
>alcyon. my shell is gulam. is it possible with gcc/gemfast/etc?

No problem at all. A full-blown GEM program can read a command line
just like any other program can. You should, however, use shel_read()
to look for a command line passed to your program from its ancestor
via shel_write(). If there's no command line in the shel_read buffer,
check for a GEMDOS command line in the basepage using the standard
argc/argv mechanism.

>i'd hate to have to do the fill with line A or directly to the screen.
>i only need white fills. this makes drawing 3-d xyz datasets (like
>FFT maps) easy if u draw from back to front. the fill eliminates hidden
>features of the plot (desirable). i have used this in full GEM progs,
>but want to use it in .ttp progs where i draw points and lines (with
>line A). don't beat me up about line A, either. if/when i get a TT,
>i will switch. as far as i know, line A is the ONLY way to draw lines
>(other than fixing pixels in Physbase) in a .ttp.

Strictly speaking, it isn't even appropiate to use line A in a TTP.
The line A routines were meant as low-level subroutines for the built
in VDI screen driver. As such, they are part of the VDI, and if you
want to avoid VDI calls, the consequence is not to use line A either
in a TTP.

As long as you don't want to publish your program in some way, you can,
however, stick to the line A method. I think you can even use VDI calls
in TTPs without major problems, but as you said before, this isn't the
kind of thing you're meant to do.

cummins@d.cs.okstate.edu (John Cummins) writes:
>How can my program find the path it was executed from if it's not
>executed from the current directory?

If it is a GEM program, you can use shel_read(), to get the full path, -
at least in TOS>=1.4.

>for example:
> A BBS program (C:\bbs\bbs.tos) calls a door program
>(C:\bbs\doors\door1\door1.tos). I want the door program to be able to find
>it's related datafiles (located in the same directory as the door1.tos file)

Again if the program is a GEM program, and it was started with shel_write,
as from the desktop, you can use shel_find() to get the path of the files.

>Seems to me this is somewhat like opening a window to a program/.rsc file,
>then opening a second window, executing the program in the un-topped window
>by ... holding down the right mouse button and then double clicking.

The .rsc file will be found, as well as other files, that shel_find() gives
you the path to...

Can you give me some of these good reasons? - and why not?
The VDI is allways running, isn't it? You can use the VDI from the AUTO folder
- before GEM have been installed or more correctly the AES.

There are many programs use form_alert(), without an appl_init(), and that is
worse isn't it?
(because the global array and probaly other structures too haven't been init'd).

These "converters" are usually called "SCSI Adapters" or so.
There are a lot of companies (i.e. ICD) offering such adapters at various
prices and with different quality (= speed) levels.

Hope this helps,
Frank

2732. RAM UPGRADES AND SOFTWARE GLITCHES

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-21 03:42:59 UTC
From: asplundm@physc1.byu.edu
Message-ID: <311asplundm@physc1.byu.edu>
Source record: 47771

This is probably an easy question to answer, but not being an Atari Guru . . .

I have a 520STfm, which I have upgraded to 2.5 M with the Z-ram board, and Samsung 80 ns 1 megabit chips (it is the 3-D board and eventually I want to put the other 2 megs in). It seems to work all right, and the z-ram Ram test program passes the memory, but I have some software problems.

There are several programs which fail to work, unless I use E-disk (the Ram Disk program) to create a 2 M ram disk which effectively gets rid of my upgrade.

1. The Note Wizard, Scale Master, Chord Magic and Rhythm Time programs from MIDImouse magic refuse to run at all.
2. Drachen (the public domain Mah Jung game) runs for a while, and then gives me 4 or so bombs.
3. El-Cal, a mathematics program, runs, but gives problems with window and memory management.

All of these problems go away if I mask out the new memory, but this is a stop-gap solution. Does anybody have any ideas? I have considered putting Tweak on the MMU, board and Video Shifter contacts, and replacing the contacts, but this problem seems might intermittent for such problems. If anybods has any ideas, please E-mail them.

>one didn't.

The HDX software won't recognize a second drive. You'll need another
driver that supports that; mine, for example, or reportedly, ICD's.
(But remember: ICD software will only run if you have an ICD
host adapter installed.)

You will also have to remove two hardware mods on the controller board.
Pin 17 and 18 of j1 are connected to ground on the board (pin 17 via
a resistor on the upper side, pin 18 via a connection on the lower
side of the board).

I don't think it is documented that you can access the VDI from a TTP
program. It _is_ documented, though, that you may use the VDI from
an AUTO folder program (note: maybe a reason why AUTO folder programs
must have the extension PRG!). To my knowledge, nothing has been said
from Atari about this issue, so some clarification from Allan might
inject the necessary facts into this thread.

TOS or TTP programs should use GEMDOS or BIOS in- and output routines,
nothing else. The TOS mode was meant for this, i.e. making ports
of character-oriented software easier.

>There are many programs use form_alert(), without an appl_init(), and that is

>How is it programmed on a standard Mega? Will programs written for the TT and 68882 run
correctly on a Mega STE and 68881?

The FPUs available for 68000 computers are programmed via registers in
memory. I don't know the base address of the FPU in a Mega, but what you
do is basically write the appropiate values into a register using move
instructions, then write the instruction into a instruction register,
and fetch the result from a result register. This is due to the fact
that the 68000 has no proper coprocessor interface like the 68020 or
68030 have.

Programs that use TT FPU will use Line F instructions that won't work
on a 68000. You may, however, write a Line F emulator for the standard
68000 to emulate a FPU coprocessor in the system.

I can give you one good reason I determined empirically. A while back I
posted a plea for help because a program would run fine from the Laser C
shell, but evnt_multi calls would not respond to the mouse, even though
they caught keyboard activity. It turned out that the program would also
run fine under gulam. But not the desktop. This program was a .ttp that
called appl_init and used vdi calls. I renamed it to .prg and voila!,
it now runs ok from the desktop. The mouse is now caught by evnt_multi.

Since my program is a port from unix and wants a parameter string, I
think I'll just create a .ttp front end to pick up the parameters and
shel_write them, then Pexec the .prg . Is there a better way?

And how should we treat GEM programs that take parameters?
Only way to get the desktop to ask for parameters is to change the extension
to TTP

I know, I know. I just switched from using an ICD adaptor to a BMS
200 adaptor on my Seagate 296N. BMS's ads are correct for my 1.5 year
old 296N - ICD's RateHD now tells me that I get the (BMS) advertised 680
- 682KB/sec throughput that 1 to 1 interleave can give you. (Oh that
dratted ICD tech "it depends on the (2XXN) drive, some work at 1-1,
some don't" _BULL!_). ICD doesn't handle these tricky drives right,
BMS does.

In any case, a FAQ here has been "are ICD-Supra BGM partitions
different from AHDI BGM partitions?" The answer is unfortunately,
frequently yes. I couldn't completely restore my 32 Meg partition
because the logical sector size went up and I lost about 3Meg of space
(in tiny files). The ICD formatter had sensed that I had TOS 1.4 (and
now 1.62) and allowed me to use the fixed-in-1.4-and-up _Unsigned_ count
of total sectors for my < 32Meg (2^42 - 1 bytes) partitions with the
logical sector size = to the physical sector size of 512 bytes.
Berkeley uses AHDI and it does exactly the trick that Allan speaks of
above. I assume that ICD and Supra do what he says for partitions
greater than 16M with Tos < 1.4 and for partitions greater than 32M
for Tos >= 1.4.

My question: can I induce the Atari partitioner to do things
the ICD-Supra way on my double sized partitions? If not, can I get
Supra's formatter and use it with my non-Supra host adaptor (legally)?
ICD's software checks for ICD HAs, so that solution is out.

This situation is irritating because of the loss of space and
because my favorite cache program won't work with BGM (logical <>

physical sector size) partitions. It's Diamond Cache. I assume - but would like confirmation - that the Atari cache program will work, but it's less fun and less configurable.

Some final BMS comments, I bought my Shoe Box off of Cove Systems, it's *very* nicely made (new back plate - mechanical stuff is well done - *keyed* scsi cables are supplied so you can't burn out the cable or even your disk), but as yet has no SCSI out connector, and is still _loud_. Any *good* suggestions on quieting a cheap Shoe Box? I managed to reformat and repartion my drive, but few drives are directly supported, and there is quite a mix of software involved. Lots of useless BMS 100 stuff is given with the new BMS 200 and AHDI stuff, I barely figured out what I needed. The docs were no help for embeded SCSI users, they need updating just as badly as the software. I'll have a big headache formatting my next drive, and will need help of some sort. Perhaps Cove got a deal on older stock? Since I finally set up an "OOP" partition for Spectre 3.0, I'm glad that I didn't need to create more than 4 partitions - Dave Small supports only the extended partitioning scheme of Supra-ICD and not the 2 tier system of AHDI.

BTW, Dave, it's not my imagination, that mouse handler can occasionally completely freeze my keyboard on my new STe, as it did more frequently on my old 520ST. That machine got progressively worse and started to freeze up in ST mode! A new IKBD processor was no help and my trying to replace the ACIA was the death of old faithful. A friend with a Mega 2 also complains that this keyboard freeze happens from time to time...

As an aside: It sounds like I'm a completely hopeless hardware hacker doesn't it? Actually I do fairly well and learn from my mistakes.

When I insert the disk with the program I was using when the keyboard went south, and rerun the program in my now rebooted Spectre - it complains that the app is damaged or open. Come on Dave! Real Macs know if the disk was just inserted and whether Multifinder is in use, and fix this particular form of file system corruption silently. I know - I trashed my only system disks that way, and recovered them by simply copying them on a real Mac - the icons did change though.

Moral of the Spectre: 8-)

Folks, *ALWAYS* _COPY_ your system disks _in_Spectre_ *BEFORE* trying to use them the first time, else my problem could *easily* happen to you 8-(. (I forgot that this was possible - even with the floppy drive problems I was having)

Sorry this got so *LONG* people, hope something comes of it 8-).

ciao,

Bob Pegram

This is correct.

stigvi@Lise.Unit.NO (Stig Vidar Hovland) writes:

>How is it programmed on a standard Mega? Will programs written for the
>TT and 68882 run correctly on a Mega STE and 68881?

No. The 68030 communicates with the FPU as a coprocessor. You use
instructions like "FSIN fp0,fp1" and the CPU communicates directly with the
coprocessor, telling it to take the sine of FP0 and put the answer in FP1.
(FP0 and FP1 are floating-point data registers in the FPU.) The 68000 does
not have this ability. With a 68000 the FPU is a peripheral, like the
sound chip or floppy-disk controller: it takes many regular 68000
instructions to read and write I/O ports on the chip to get it to do what
you want. You have to do it "by hand" instead of having the CPU do it for
you. Thus, it is slower and your program is larger than it would be using
68030 FPU instructions.

What Claus is saying is that there is an FPU peripheral that plugs into the
Mega ST (called the SFP004), and there is an FPU that comes with the Mega
STe, and they interface the same way. They both interface in the
"peripheral" way, because that's the only way the 68000 can handle. This
means that a program (or library) that runs on a Mega using the SFP004 will
run on a Mega STe and use its built-in FPU. In the TT the FPU interfaces
in the "coprocessor" way, so these programs won't work.

Either use a CLI after desktop, a cooler desktop (ie: Gemini!!!), or write
a .PRG that asks for parameters then runs your program and passes the
parameters you just entered (sounds like it might be short, quick, weekly
for Double Click eh?)...

Ok, here' is one: Did you ever use Gemini (or any other cli)? If you start
a .TOS (or .TTP) using VDI, you'll have a lot of garbage on the screen.
Not to speak of using these programs (TOS with VDI calls) in a multitasking
environment (MINT, MultiGem)

Yes it is. In an STReport from about three months back they included the
instuctions someone had posted on CIS. You might try contacting STR re:
back issues. It's apparently not too hard a thing to do. I just got a
Golden Image opto-mechanical and I love it! _Almost_ as good as a
Microsoft I tried out in the store. Funny that the guy at CIS said the
same thing after he got a fully optical mouse from Golden Image.

This does not solve the problem, if I buy a commercial program like
1st word, adimens (exec.prg and init.prg) that accepts parameters
I would like to be able to give them even from the standard desktop
So the desktop should provide the oppurtunity to do so.
I understand that renaming it to .TTP is not the right way. But can't I
fool around in the desktop.inf file to make the desktop ask for parameters
for a GEM program and still startup that program as a GEM application?
May be use the extension GTP or so?

Actually I believe I once did this but I forgot how I did it and I like to
know if I did it rigth.

2747. GEMFAST 1.5

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-23 03:36:02 UTC
From: steve@thelake.mn.org
Message-ID: <A3028358870@thelake.mn.org>
Source record: 47787

Good news for Sozobon users!

I have just mailed GEMFAST 1.5 off to atari.archive.umich.edu.

Included are:

GEMFST15.LZH GEMFAST 1.5 libraries for Sozobon, Alcyon, assembler
the binary aesfast.a and vdifast.a files, with .h, docs

GEMFUT15.LZH GEMFAST 1.5 utilities, extensions in C source code form

GEMFXM15.LZH GEMFAST 1.5 example programs, C source code

The last file includes an easy-to-use module for ``thermometer''
progress displays, similar to the Desktop's disk formatter. Read the
code as well as the documentation, because the docs are wrong. :-)

I have not yet located the version 1.5 GEMFSC (MadMac assembler
source) file, and indeed I don't even know if Ian Lepore released it.
If anybody has the sources, PLEASE make them available.

(DISCLAIMER: The use of LZH does not constitute an endorsement. That
is the format in which I received the files. I still consider LZH a
disaster area.)

On a different note, I also have the Atari XCONTROL.ACC and related
files, which (finally!) has been released for those of us who don't
own TT030 or Mega STE machines. If no one has yet uploaded that
archive, I can send it. I'm running it right now under TOS 1.4 and,
so long as I don't let it load the TT and STE-specific sound and
window color CPX modules, it works fine.

If you install a GEM program keyed to a particular file or file type, clicking on such a file will pass its name to the .PRG as an argument. For example, if you install 1st_WORD.PRG and specify .DOC files, if you double-click on MYFILE.DOC the result will be the same as a command line of:

1ST_WORD MYFILE.DOC

If you want to pass a more complex argument -- with switches, for instance -- you'll just have to get a better Desktop. I second Aaron's recommendation of Gemini.

With Gemini, you can write a little shell script that shuffles arguments around and passes them to a program. The shell script then can be dragged out onto the desktop, renamed something more informative (8+3 filenames are not needed for aliases of shell scripts). Drag a file (or multiple files) to the script's icon and let go. The script then launches the .PRG appropriately.

I don't know of any GEM applications that process command-line switches, but I intend to put them into the next version of UUCODER.

2750. Mono Monitor.... HEY YOU!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-23 21:49:34 UTC
From: scott@cs.odu.edu
Message-ID: <SCOTT.91Jun23164934@breeze.cs.odu.edu>
Source record: 47790

Hello? I know there are people out there, I see YOUR posts...

Thank you J. R. Bammi for replying to my query about the capicitor
that needs to be replaced in the mono monitor. JR told me to look for
a completely fried capicitor... well, I am using my mono monitor now.
I have decided to leave my monichrome monitor on until the capicitor
blows because no one else has replied as to which one it is.

IS IT THE 220uF which is rated at 16V what is on the power board?
If not, hell, there are hundreds of capicitors in there.

Next point of interest--

Hello? Has anyone ever installed the overscan mods into a 1040st
Hello?

This is what the doc says:
How to connect and wire the Overscan-change-over-switch:

Directly at the Emitter of the Composite Sync signal driver Transistor
You pick up the buffered Composite Sync Signal and feed it to the third
pin of the switch.
The second pin of the switch (the pin in the middle) goes to the pin 37
of the Shifter and pin 52 of the MMU.
The first pin of the switch is connected to pin 39 of the Glue (Display
Enable Signal)
Reminder: the MFP 68901 pin 20 still gets the Display Enable Signal in
both modes !!!
We have tried to use also the Composite Sync for the Timer B-Input in
Overscan mode, but then the ST doesn't boot himself after a Reset !

Now, I think I can figure out WHAT needs to be done, but alas, I don't
know the "where." I do not have a schematic of the 1040 and the
digitized images with overscan all appear to show the 520 (with RF)
upgrade which I thought the docs said required more hardware.

From what I gather, all I need to do is locate:
1) A two position switch (3 pin).
2) DEs from shifter pin 37.
3) MMU pin 52

both 2 and 3 go to the central pin of the switch....

4) pin 1 of the switch goes to pin 39 of the GLUE (DEs?).
5) pin 3 of the switch goes to Composite Sync.

I don't know which chips are GLUE and MMU.... Or where the composite Sync is. I will try to inspect the chips a little closer after this post goes out.

What was all that about messing with the hsync and vsync of the monitor? I put electronic tape down the shaft of a long screw driver in preparation for this upgrade, but it looks as if it all is done inside the ST.

Does one have to mess with the H/V sync, or whatever, inside the mono monitor? At least those parts are clearly labelled.

Hey, if you know anything about this, please don't assume someone else will reply. So far in six months of posting questions here, I have received replies from three people... none of which have been complete. Please let me know if you have done this mod.

One last note, from what I read in the overscan docs, it looks like it explained a problem my color monitor has.... when I turn up the contrast and brightness level all the way (the only way I can get to see most of the colors) the back of the screen is no longer black, it is an off red-brown and I get these ugly diagonal lines that look like scan lines... .but they are different, they run from the lower left to the upper right... I would guess that there are like 10-20 of them. THey don't move, but they are definitely there. The docs seem to suggest that these are verticle blank "flyback" traces. I was under the impression that during the verticle blank time, there was no display signal, so there would not be and "loose" traces..... Does anyone have any ideas about this? It's really annoying since I need to turn up the contrast and brightness levels all the way just to be able to see some text and colors in most programs.

HELLO?
"Is anyone out there?"

Scott

2751. DS1216E Time Chip Problems

Newsgroup: comp.sys.atari.st.tech

Source record: 47693

Arg! I tried to install a ds1216E time chip in my Atari 1040STf and it doesn't fit, even cutting the power supply doesn't work. However, bright idea! I have a two chip TOS set, which means I have 4 open slots where the full 6 chip TOS would normally go. Question: can I solder the DS1216E socket/chip into one of the open slots and have it work. Or od you need to have a TOS chip plugged into it, or did Atari bastardize the thing so only the two slots where the TOS chips are work? Help, soon, please!

The first thing would be to attempt to get the Desktop to handle the problem
(ie. GEM Take Parameters).

If this is not possible, then simply write a program (called, say, "GTP.PRG"),
that takes a program as a parameter, pops up a "parameters" box, then runs
the program with those arguments. Then, simply use Install Application to
make "GTP.PRG" the processor for all "*.GTP" programs.

>

Or if you use a desktop alternative program, like Gemini (I triple the
recomendation), and you want to pass more than one files to a GEM
application (with its icon already on the desktop), just select the icons
of the files (with Shift+Click) and drag them to the icon of the application
(on the desktop).

BTW, I think there is no need for changing the standard desktop just because
it is "difficult" to pass parameters in GEM programs.The "Install Application"
entry is more than enough, and it works very well. Now, if one wants to pass
more than 1 parameters to programs frequently, he should use a command line
anyway.

In addition, I don't like the idea of the built-in(in GEM programs) parameter
box either. It would work well if the parameters (talking about files only,
no switches) lied in the same directory with the program; otherwise the user
should type the full path of the files (and even if there are only 2 of them it
would be tedious to type the whole path name for each). Now, if there is a GEM
program that expects (unix like) switches it should be recoded using curses
instead of GEM.

If my message sounds abnoxious I apologise...I didn't mean it.

PS. BTW, has anyone tried the demo of my phone-address catalog program called
ATZENTA2 ? I'm interested in suggestions and comments (of any kind 8*)
I'm just trying to figure out if it's worth it to keep improving it or
just port it to another machine...

|I don't know what I'm doing wrong but I can't seem to get fast screen
|updating routines like the ones used in Elvis or Levee. Can someone
|enlighten me on the technique used. Maybe even the screen module.

I don't know about elvis, but the way levee does fast screen updating
is via a combination of semi-deranged update optimisation and cutting
way down on the number of write() calls (so I can run it from the modem
port) When levee starts up, I allocate a large buffer [ROWS*COLS+FUDGE],
then for my redrawing, I write the *entire* update into the buffer - including
terminal control - then write() it out in one fell swoop. It's pretty close
to the speed of Bconout(), plus it's redirectable to other devices.

The screen updating, btw, is the only really good bit of levee - some of
the file-io and internal file managing code is, well, just about as bad as
you can get and still have working code (chedit has "abandon all hope" written
over it - this warning also applies to levee.)

That's the reason why Atari came up with a new program type with extension
GTP in TOS 2.x and 3.x. Nonetheless, your point is valid. This is a real
problem in the old TOS versions.

>one didn't.

The problem is not the hardware, its a software problem: I suppose that you
are using the AHDI; the driver is not written for recognising a second drive
(at least in versions <= 3.01), so all you have to do, is patching the AHDI
or getting another driver which handles two drives correctly.

.NTP stands for Neodeskt takes parameters an is used for programs that
hook in to Neodesk for some routines.
But your right there is a possibility to install something like .GTP

++Either use a CLI after desktop, a cooler desktop (ie: Gemini!!!), or write
++a .PRG that asks for parameters then runs your program and passes the
++parameters you just entered (sounds like it might be short, quick, weekly
++for Double Click eh?)...
+
+This does not solve the problem, if I buy a commercial program like
+1st word, adimens (exec.prg and init.prg) that accepts parameters
+I would like to be able to give them even from the standard desktop
+So the desktop should provide the oppurtunity to do so.
+I understand that renaming it to .TTP is not the right way. But can't I
+fool around in the desktop.inf file to make the desktop ask for parameters
+for a GEM program and still startup that program as a GEM application?
+May be use the extension GTP or so?
+

you can install a program like first word as an application accepting
files with *.DOC extenders. Thus, whenever you double click on such
a file, the commandline that is sent to 1st word by the desktop already
has the filename in the commandline. this may not be the most elegant
way of passing a commandline to a gem program, but it is accesable from
the standard desktop. note as well that this method of passing a commandline
only works for passing the name of only a single file, nothing more, nothing
less. DC, where are you????!!!!! :=) :=)

It may or may not have been fixed, but because even people with TOS 1.2 and (gasp!) TOS 1.0 want to be able to use large partitions, HDX goes to BGM at 16MB for maximum compatibility. Otherwise you could take a 31MB, non-BGM partitioned disk to a machine running TOS 1.2 and not be able to get at the files.

Get a Mega STe or a TT :-) The new Desktop in these machines allows GEM programs to take parameters. You can either drop a file onto a PRG icon (to start that program with that file name as its paramenter) or install the application as "GEM Takes Parameters" and double-click it, at which time you'll be solicited for parameters just like a TTP.

If one wants to create a new program type like GTP (GEM Takes
Parameters) it seems to me that all you'd have to do is rename
the appropriate programs with the GTP extent and then write a
little program to pop up a dialog requesting the command line and then
executing the program. It would be an "Installed Application". If
anyone is interested, I'll write such a beast as it wouldn't take that long.

Well, there is room to put a 3.5" drive in a Megafile30. I have fixed a couple of signal pins and bought cables to run two drives, used another power supply to the second drive, fixed the terminator and the drive number assignment, and the drives run marvellously. So far so good.

Is there a convenient way to fix the power supply module so that it can generate 4 amps? The diode there seems to pass only 2 amps of 5V, though.

Cheers,
Tsuji

I don't know if everyone is familiar with it, but DC Desktop does the same thing everyone is asking about. You can use DC Install to make it prompt for parameters for any application, not just .TTP, and I use it regularly like this for DevPac ST, 1st Word and all of my archivers. DC Desktop is selling around here for as low as $22, so it might be worth it just to pay the ducats if the feature is that important...

(I have to admit, I'm still using v1.0 of DCD, so there may even be some improvements to the system since I've been introduced to it)

2768. hooking 1520 plotter to ST, problems with

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-24 22:37:29 UTC
From: cliff@jarthur.Claremont.EDU
Message-ID: <12241@jarthur.Claremont.EDU>
Source record: 47702

I'm trying to hook up my Commodore 1520 plotter (the old C64 color plotter) to my ST. I've built the cable--I'm going to plug it in to my parallel port-- and now I just need to send it the proper signals. Since the C64 uses a serial data bus, I will have to send eveything bit by bit. After looking through my C64 Programmer Reference Guide, I found out the timing signals I need. The trouble is, I need to send signals 20 micro-seconds long through the parallel port. I was gonna do this through the IO port B on the sound chip but I forsee several problems:

1. Can the port handle signals this fast? After looking through my printer (centronics) manual, it looks like this shouldn't be a problem.
2. The biggie: How can I time my code for these types of signals. It looks as if I am going to have to count clock cycles. I'm trying get get my hands on a 68000 manual and haven't had much luck yet. Is there another way, possibly by using the sound chip or maybe something else to count micro-seconds or even 20 micro-second intervals? Obviously I'm doing this in assembly.

If everything works right, I will hopefully patch the Bconout() bios call and provide myself with another device type. I would prefer to use my cartridge port for this type of thing so I wouldn't have to unplug my printer so often, but from what I hear it is difficult to write to the cartridge port (I know it can be done, though. There was an article in STart). Is it so bad?

Once I get this working, I suppose I could even hook up my 1541. Joy! Rapture!

Thanks for any help.

I have to admit that NeoDesk 3 is really good...but ironically I have exactly
the oposite feelings. I never had confindence in NeoDesk (here I have to say
that I have never used NeoDesk extensively, since I don't own a copy of it.
I've worked on it periodically being in a friend's house). But I think that
everyone will agree that Neodesk became stable enough only after version 2.00.

On the other hand, Gemini was very stable from the very first version (for
me at least), and the current (2nd) version (1.21) is simly fantastic.
NeoDesk 3 defenitly has more features than Gemini 1.21, but costs a lot more.
IMHO the ratio performance/price of Gemini is way larger than Neodesk's.

Don't get me wrong, I don't want to start a flame war. It's just my oppinion.
I think both programs are in the top ten of ST's software, and both worth
every penny of their price. I just happen to like Gemini better.

PS. BTW, everyone should get a copy of XCONTROL.ACC (Atari's new control panel)
I think this time Atari did a remarkable job. Defenitly the best control
panel around!!!!!!

2770. stos, again

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-25 03:45:05 UTC
From: scott@cs.odu.edu
Message-ID: <SCOTT.91Jun24224505@breeze.cs.odu.edu>
Source record: 47709

Hello, I found the stos 2.06 support files on Atari archive...

I download them and ran the upgrade programs for
the stos basic ans stos compiler.... using a copy
on disk a.

The basic seemed to be upgraded successfully and work.

MY MOUSE WORKS!

My old compiler wont compile the new basic...
I get unknown extension.

I upgraded the compiler.
My new compiler STILL won't compile the new basic
I get "unknown extension"
the line is a line that I don't have in my program and there is usually
the command "extension #C" on the line.

PLEASE HELP ME!

Scott

2774. Hard-Disk Construction Summary Request

I am thinking again about building a hard drive for my ST. I have an ancient 10 MB Supradrive in a shoe box case. I was thinking about reusing the case & power supply & tossing a new drive in there.

Can some kind people please send me infomation about any/all of the following questions:

(1) What host adapters are available, where can I get them, how much do they cost, what are the differences?
(2) What drives do people recommend? Where is a good source to purchase drives?
(3) Where can I get the specification of the data output by the DMA port (what people refer to as ASCI I think)?
(4) What kind of software would I need to write/obtain to make this work"?

Any information would be greatly helpful. Is there a "Frequently Asked Questions" kind of wqrite up about building hard drives for the ST?

If you run it from a shell just leave it named .prg.
A program doesnt have to be named .ttp to take parameters. You can pass
them anyway. This is only difficult if you try to do it from the desktop.

2776. Folder information (How they are handled)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-25 20:31:15 UTC
From: jharres@sleepy.bmd.trw.com
Message-ID: <1555.286745a3@sleepy.bmd.trw.com>
Source record: 47715

My hard drive hiccuped and now I can't open one of the folders. It responds with three bombs and requires a shutdown to recover (reset doesn,t help).
My questions are :
1. How are folders handled on a disk, including format of size, name, and locaton data?

2. How are the files within a folder found (where they are on the disk)?

3. If you don't know, how do you determine the starting address of a file on the disk?

If you haven't guessed, the one file I need and haven't backed up is within the bad folder. I can go in with a sector editor and look at all sectors on this partition which makes me believe that only a pointer or related bit of file information has been corrupted and not the file itself. By the way it's a Syquest cartridge drive with an ICD plus adapter.

Thanks for any help you might provide

Jim Harres jharres@doc.bmd.trw.com

2777. Re: passing to PRG (was: Re: requirements to use VDI)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-25 21:59:33 UTC
From: rosenkra@convex.com
Message-ID: <1991Jun25.215933.22514@convex.com>
Source record: 47717

i started this discussion by asking about using VDI calls in an otherwise ordinary .ttp program. i have gotten lots of (good) feedback. but perhaps i should specify exactly what i want to do...

these days i write exclusively .ttp programs, i.e. those which would normally be executed from a CLI (currently i still use gulam). i want a few of these programs (like the recently posted mgif - it did appear, did it not; i have been away for a few days and things expire quickly here) to do a certain amount of graphics, like lines, dots, and polygon fills. i have been using line A for lines/points since it is so simple to do so. however, now i need to do fills of irregular polygonal areas. this is possible with line A, but the hassle of writing a front end to $A006 or whatever (one scan line at a time fill) leads me to see if i can use the much simpler v_fillarea (or whatever it is called). this is the ONLY vdi routine i want to call at present.

it sounds like i can do basically

graf_handle (or whatever)
v_opvwrk (or whatever it is)
v_fillarea

which is still nice and simple. i realize that it may cause problems if GDOS is installed. since i do not have it, that doesn't bother me :-). i also want to minimize the amount of overhead, though i suspect linking in vdibind will add more than a little overhead.

i still want the program to feel like a curses-like application (no mouse) and want command line args. i also realize that i can hand blit directly to Physbase or my screen memory whatever the heck i want, but i don't need the expense (in time) of writing routines to flip bits (which, admittedly, aren't THAT hard).

is there a better solution? what will break if i do the above (so far it looks like GDOS)? what are the restrictions? i have no interest in making this a GEM program at this time. as it is now, it should port fairly easily to X (maybe not so easily), Sunview (just draw a rasterfile in memory), etc. making it GEM will ruin this attribute (which, religiously, i consider far more important than having a mouse just to point+click rather than key a 1-2 char command code which, for me, is faster anyway). in fact, to further fuel the ensuing amiga/atari flame war or skirmish, one of the things i most like about the ST is it is SO easy to port unix software. and there are many good csh/sh/etc clones available. i don't care about number of colors since the SM124 is about the nicest monitor i have ever seen (often overlooked in flame wars). my eyes thank atari for this one!

this brings up another question: are "flicker" screens possible on things like monochrome Suns? how fast can u change full-screen raster images from memory to the frame buffer (/dev/fb, i presume, for mono)? the equivalent of:

```
do {
Setscreen (scrn1, scrn1, -1); Vsync ();
Setscreen (scrn2, scrn2, -1); Vsync ();
Setscreen (scrn3, scrn3, -1); Vsync ();

} while (!char_pressed_or_equivalent_interrupt);
```

which runs at at least 10-20 Hz on the ST (guess). since i no longer have a sun, this may be more academic than practical. when i had a sun 3/50 i 1) operated it like a big vt100 (no squinting to make out those 6x8 fonts or whatever when u have chars 1/4" high and u'd be suprised just how productive ^Z and ~^Z and fg can be :-), 2) prefered mono to color (save my poor eyes!). in fact since the 3/50 under SunOS 4.0 was such a dog when trying to run sunview with only 4 MB (and slow page/swap SCSI disk), i had little choice anyway. only the brief excursion to the land of windows for a few thousand games of backgammon (gammontool) :-).

>or getting another driver which handles two drives correctly.

does this mean that daisychaining an SH204 off a megafile 60 (it has both
in and out ACSI ports) using AHDI 3.01 (what i think i am using now)
will not work either no matter what the LUN switches are set to? is there
a more recent AHDI which will recognize the other drive? i was going to
try this, having finally backed up all 58 MB of stuff on my '60 (file-by-file
no less, to floppies :-( ). short of this, how can i get CBDI from claus
in the states?

I just downloaded ghostscript the other day and have loaded it into
my E: drive under \ghostscr.ipt directory. In my cli (MT-C shell) I've
set GS_LIB to both e:/ghostscr.ipt and e:\ghostscr.ipt in the profile.
I try to print one of the example files as 'gs chess.ps' and get:

```
reading ghost.ps (Printing in memory, please ..etc)
ghost.ps read
Cant find Fontmap!
(copyleft info)
GS<4> (and a prompt)
```

What am I doing wrong? What's this fontmap it's looking for?

Might be that you had installations problems. Fact is, that Gemini did
work on all graphics cards and on the TT since day one. You can't say that
about Neodesk (does it still use Line-A? Does it still acces the disk
with BIOS calls? Does it still use the border areas of windows????)

The fontmap file maps between the PostScript font names (e.g. /Times-Roman) and GhostScript font FILES (e.g. ptmr.gsf). It live in the ./fonts subdirectory. Now, to make the rest of it work, you need to modify your GS_LIB variable:

GSLIB=e:\ghostscr.ipt\fonts,e:\ghostscr.ipt\ps

Basically, it's a search path for any file GS wants to open. Can't remember if the slashes face forward or back (forward in the variable, backwards on the command line?).

++ What am I doing wrong? What's this fontmap it's looking for?

If anyone else sees this error, it's covered in the readme file. The GS_LIB
env-var hold the pathnames to the subdirectories 'ps' and 'fonts' and should be
(in the example) e:/ghostscr.ipt/ps,e:/ghostscr.ipt/fonts.

BTW - The postscript generator in the software suite accompanying the Yale
Bright Star catalogue appears to generate valid PS files. Ghostscript
successfully produces prn_1000 files from the PS output. Looks good.

Such a configuration will work with AHDI, no problem. The trouble begins
when you try to connect a second drive to a SH204's or a Megafile's controller.

>a more recent AHDI which will recognize the other drive? i was going to

Unfortunately, we have no US/UK version of the book because we cannot
find someone to translate it. We also haven't got a US/UK distributor
(who in the world would distribute a German book in the US?); so the
only way to get the software (which is part of the book) is to order
a copy directly from me. 'Nuff advertising now 8-)

Hm, are there supposed to be more font files with the distribution? The
only one in the distrib I got was UGLY(something).GSF. So .GSF files
have to live in a FONTS directory. To keep my path uncomplicated, I put
the GS executable in the \bin subdirectory. Does my fontmap file have
to live there too or will it suffice to keep put it in some directory
pointed to by GS_LIB?

The fontmap file needs to be in the GS_LIB path. Regarding fonts, there are no further .gsf fonts in the distribution, but they are freely available from various ftp sites. You can also make them yourself from .bdf fonts on Unix.

>is installed. since i do not have it, that doesn't bother me :-). i also want
Shouldn't interfer with GDOS at all, GDOS is only needed if you use other
ouput devices than the screen itself, or want to use different fonts

>to minimize the amount of overhead, though i suspect linking in vdibind
>will add more than a little overhead.
Depends on your compiler since only thing you have to do is a trap
for the functions you use the only overhead
is filling some internal VDI arrays, it is not that much

VDI is not difficult to handle once you learned what the functions do
AES use windows is a lot more difficult, because you can't do it partial

>will not work either no matter what the LUN switches are set to? is there
>a more recent AHDI which will recognize the other drive? i was going to

No but daisy chaning a SH204 to any other atari disk will give other problems
When I tried this a few years ago everything seemed fine but when I tried
to transfer megabytes from one HD to the other I started to lose files
they got corrupted and finally I lost alll data on the SH204 because of
a corupted FAT (I did use AHDI 3.01 at that time)
According to Atari there is a timing problem between the SH204 and newer
atari HD's which means the SH204 cannot be connected to any of the Atari
drives. (well that's what they say)

2793. Latest Picture Formats List (Lots of Changes!) [LONG]

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-27 03:12:17 UTC
From: dmb@wam.umd.edu
Message-ID: <1991Jun27.031217.23884@wam.umd.edu>
Source record: 47733
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

After several months of neglecting to update the list, I've made all the changes that were in the queue all at once. Here's a summary of what's new and improved, and who contributed what:

o Clarification made to IFF format (Jim Omura)
o Spectrum Smooshed (*.SPS) format added (Shamus McBride)
o Lars Michael's RGB Intermediate (*.RGB) format added (Lars Michael)
o ComputerEyes Raw Data (*.CE?) format added (G. "Maddog" Knauss)
o Animaster Sprite Bank (*.ASB) format added (Neil Forsyth)
o STOS sprite (*.MBK) format added (me)
o Cyber Paint Sequence (*.SEQ) format added (me)

Thanks to everyone who's contributed info in the past few months! Also, if I've left something out, don't hesitate to let me know. I think I got all the changes that were "on the stack" in there, but I may have missed something, so don't be bashful if I've left you out.

As always, everyone is encouraged to replace older versions of The List with this one. This time around it's particularly important since so many changes have been made.

Thanks all,

Dave Baggett

PackBits Compression Algorithm

Introductory Information
----
word = 2 bytes

long = 4 bytes
palette = Hardware color palette, stored as 16 words. First word is color register zero (background), last word is color register 15. Each word has the form:

```
Bit: (MSB) 15 14 13 12 11 10 09 08 07 06 05 04 03 02 01 00 (LSB)
-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --
0 0 0 0 0 R2 R1 R0 0 G2 G1 G0 0 B2 B1 B0
```

R2 = MSB of red intensity
R0 = LSB of red intensity

G2 = MSB of green intensity
G0 = LSB of green intensity

B2 = MSB of blue intensity
B0 = LSB of blue intensity

Intensity ranges from 0 (color not present) to 7 (highest intensity).

Example: { red = 7, green = 3, blue = 5 } -> 0735 (hex)

Caveat: It is wise to mask off the upper four bits of each palette entry, since a few programs store special information there (most notably Art Studio).

The Formats

<NEOchrome> *.NEO

1 word flag byte [always 0]
1 word resolution [0 = low res, 1 = medium res, 2 = high res]
16 words palette
12 bytes filename [usually " . "]
1 word color animation limits. High bit (bit 15) set if color animation data is valid. Low byte contains color animation limits (4 most significant bits are left/lower limit, 4 least significant bits are right/upper limit).
1 word color animation speed and direction. High bit (bit 15) set if animation is on. Low order byte is # vblanks per step. If negative, scroll is left (decreasing). Number of vblanks between cycles is |x| - 1
1 word # of color steps (as defined in previous word) to display picture before going to the next. (For use in slide shows)
1 word image X offset [unused, always 0]
1 word image Y offset [unused, always 0]
1 word image width [unused, always 320]
1 word image height [unused, always 200]
33 words reserved for future expansion
16000 words picture data (screen memory)

32128 bytes total

<NEOchrome Animation> *.ANI

NOTE: To get this feature on versions 0.9 and later select the Grabber
icon and click both mouse buttons in the eye of the second R in the
word GRABBER.
Interestingly enough, some versions of NEO only require you
to press the right button, not both. Hmmm...

1 long magic number BABEEBEA (hex) (seems to be ignored)
1 word width of image in bytes (always divisible by 8)
1 word height of image in scan lines
1 word size of image in bytes + 10 (!)
1 word x coordinate of image (must be divisible by 16) - 1
1 word y coordinate of image - 1
1 word number of frames
1 word animation speed (# vblanks to delay between frames)
1 long reserved; should be zero
----
22 bytes total for header

? words image data (words of screen memory) for each frame, in
order

<DEGAS> *.PI1 (low resolution)
*.PI2 (medium resolution)
*.PI3 (high resolution)

1 word resolution (0 = low res, 1 = medium res, 2 = high res)
Other bits may be used in the future; use a simple bit
test rather than checking for specific word values.
16 words palette
16000 words picture data (screen memory)

32034 bytes total

<DEGAS Elite> *.PI1 (low resolution)
*.PI2 (medium resolution)
*.PI3 (high resolution)

1 word resolution (0 = low res, 1 = medium res, 2 = high res)
Other bits may be used in the future; use a simple bit
test rather than checking for specific word values.
16 words palette
16000 words picture data (screen memory)
4 words left color animtion limit table (starting color numbers)
4 words right color animation limit table (ending color numbers)
4 words animation channel direction flag (0 = left, 1 = off, 2 = right)
4 words 128 - animation channel delay in 1/60's of a second. [0 - 128]
(I.e., subtract word from 128 to get 1/60th's of a second.)

32066 bytes total

<DEGAS Elite (Compressed)> *.PC1 (low resolution)
*.PC2 (medium resolution)
*.PC3 (high resolution)

1 word resolution (same as Degas, but high order bit is set;
i.e., hex 8000 = low res, hex 8001 = medium res,
hex 8002 = high res). Other bits may be used in the
future; use a simple bit test rather than checking
for specific word values.
16 words palette
< 32000 bytes control/data bytes
4 words left color animation limit table (starting color numbers)
4 words right color animation limit table (ending color numbers)
4 words animation channel direction flag [0 = left, 1 = off, 2 = right]
4 words 128 - animation channel delay in 1/60's of a second. [0 - 128]
(I.e., subtract word from 128 to get 1/60th's of a second.)

< 32066 bytes total

Compression Scheme:

PackBits compression is used (see below). Each scan line is compressed
separately; i.e., all data for a given scan line appears before any data
for the next scan line. The scan lines are specified from top to bottom
(i.e., 0 is first). For each scan line, all the data for a given bit plane
appears before any data for the next higher order bit plane. Note that this
is identical to the IFF 'BODY' image data.
To clarify: The first data in the file will be the data for the lowest
order bit plane of scan line zero, followed by the data for the next higher
order bit plane of scan line zero, etc., until all bit planes have been
specified for scan line zero. The next data in the file will be the data
for the lowest order bit plane of scan line one, followed by the data for
the next higher order bit plane of scan line one, etc., until all bit planes
have been specified for all scan lines.

Caveats:

DEGAS Elite's picture loading routine places some restrictions on
compressed DEGAS files:

o Elite uses a 40-byte buffer to store data being decompressed.

o Whenever a control command is encountered, bytes are stuffed
in this buffer.

o The buffer is only emptied when there are EXACTLY 40
characters in it.

The important conclusion here is that

No control command may cause the buffer to have more than 40
bytes in it. In other words, all control commands must end on
or before the 40-byte boundary.

Any picture violating the last condition will cause Elite to get a bus error when the picture is loaded.

<Tiny> *.TNY (any resolution)
*.TN1 (low resolution)
*.TN2 (medium resolution)
*.TN3 (high resolution)

Several people have reported sightings of mutated Tiny pictures that do not follow the standard format, so let's be careful out there. What is described here is the format that David Mumper's original TNYSTUFF.PRG produces.

1 byte resolution (same as NEO, but +3 indicates rotation information also follows)

If resolution > 2 {
1 byte left and right color animation limits. High 4 bits hold left (start) limit; low 4 bits hold right (end) limit
1 byte direction and speed of color animation (negative value indicates left, positive indicates right, absolute value is delay in 1/60's of a second.
1 word color rotation duration (number of iterations)
}

16 words palette
1 word number of control bytes
1 word number of data words
3-10667 bytes control bytes
1-16000 words data words

42-32044 bytes total

Control byte meanings:

For a given control byte, x:

x < 0 Absolute value specifies the number of unique words to take from the data section (from 1 to 127)
x = 0 1 word is taken from the control section which specifies the number of times to repeat the next data word (from 128 to 32767)
x = 1 1 word is taken from the control section which specifies the number of unique words to be taken from the data section (from 128 - 32767)
x > 1 Specifies the number of times to repeat the next word taken from the data section (from 2 to 127)

Format of expanded data:

The expanded data is not simply screen memory bitmap data; instead, the data is divided into four sets of vertical columns. (This results in better compression.) A column consists of one specific word taken from each scan line, going from top to bottom. For example, column 1

consists of word 1 on scanline 1 followed by word 1 on scanline 2, etc.,
followed by word 1 on scanline 200.
The columns appear in the following order:

1st set contains columns 1, 5, 9, 13, ..., 69, 73, 77 in order
2nd set contains columns 2, 6, 10, 14, ..., 70, 74, 78 in order
3rd set contains columns 3, 7, 11, 15, ..., 71, 75, 79 in order
4th set contains columns 4, 8, 12, 16, ..., 72, 76, 80 in order

Note that Tiny partitions the screen this way regardless of resolution; i.e.,
these aren't bitplanes. For example, medium resoltion only has two bitplanes,
but Tiny still divides medium resolution pictures into four parts.

<Spectrum 512> *.SPU

80 words first scan line of picture (unused) -- should be zeroes
15920 words picture data (screen memory) for scan lines 1 through 199
9552 words 3 palettes for each scan line (the top scan line is
not included because Spectrum 512 can't display it)

51104 bytes total

Note that the Spectrum 512 mode's three palette changes per scan
line allow more colors on the screen than normally possible, but a
tremendous amount of CPU time is required to maintain the image.

The Spectrum format specifies a palette of 48 colors for each scan line.
To decode a Spectrum picture, one must be know which of these 48 colors
are in effect for a given horizontal pixel position.

Given an x-coordinate (from 0 to 319) and a color index (from 0 to 15),
the following C function will return the proper index into the Spectrum
palette (from 0 to 47):

```
/*
* Given an x-coordinate and a color index, returns the corresponding
* Spectrum palette index.
*
* by Steve Belczyk; placed in the public domain December, 1990.
*/
int
FindIndex(x, c)
int x, c;
{
int x1;

x1 = 10 * c;

if (1 & c) /* If c is odd */
x1 = x1 - 5;
else /* If c is even */
x1 = x1 + 1;
```

```
if (x >= x1 && x < x1 + 160)
c = c + 16;
else if (x >= x1 + 160)
c = c + 32;

return c;
}
```

<Spectrum 512 (Compressed)> *.SPC

```
1 word flag word [$5350 or "SP"]
1 word reserved for future use [always 0]
1 long length of data bit map
1 long length of color bit map
<= 32092 bytes compressed data bit map
<= 17910 bytes compressed color bit map
--------------
<= 50014 bytes total
```

Data compression:

Compression is via a modified run length encoding (RLE) scheme, similar to DEGAS compressed and Tiny. The data map is stored as a sequence of records. Each record consists of a header byte followed by one or more data bytes. The meaning of the header byte is as follows:

For a given header byte, x:

```
0 <= x <= 127 Use the next x + 1 bytes literally (no repetition)
-128 <= x <= -1 Use the next byte -x + 2 times
```

The data appears in the following order:

1. Picture data, bit plane 0, scan lines 1 - 199
2. Picture data, bit plane 1, scan lines 1 - 199
3. Picture data, bit plane 2, scan lines 1 - 199
4. Picture data, bit plane 3, scan lines 1 - 199

Decompression of data ends when 31840 data bytes have been used.

Color map compression:

Each 16-word palette is compressed separately. There are three palettes for each scan line (597 total). The color map is stored as a sequence of records. Each record starts with a 1-word bit vector which specifies which of the 16 palette entries are included in the data following the bit vector (1 = included, 0 = not included). If a palette entry is not included, it is assumed to be zero (black). The least significant bit of the bit vector refers to palette entry zero, while the most significant bit refers to palette entry 15. Bit 15 must be zero, since Spectrum 512 does not use palette entry 15. Bit 0 should also be zero, since Spectrum 512 always makes the background color black. The words specifying the values for the palette entries indicated in the bit vector follow the bit vector itself, in order (0 - 15).

NOTE: Regarding Spectrum pictures, Shamus McBride reports the following:

"... [The Picture Formats List] says bit 15 of the color map vector
must be zero. I've encountered quite a few files where [bit 15] is
set (with no associated palette entry)..."

<Spectrum 512 (Smooshed)> *.SPS

This format compresses Spectrum 512 pictures better than the standard
method. There are at least two programs that support this format, SPSLIDEX
and ANISPEC, although the two seem to differ slightly in their interpretation
of the format.
One point of interest: Shamus McBride deciphered this format without an ST!

1 word 5350 (hex) ("SP")
1 word 0 (reserved for future use)
1 long length of data bit map
1 long length of color bit map
<= ? bytes compressed data bit map
<= ? bytes compressed color bit map

< ? bytes total

Data compression:

Compression is via a modified run length encoding (RLE) scheme,
similar to that used in Spectrum Compressed (*.SPC) pictures.

The data map is stored as a sequence of records. Each record consists of a
header byte followed by one or more data bytes. The meaning of the header
byte is as follows:

For a given header byte, x (unsigned):

0 <= x <= 127 Use the next byte x + 3 times
128 <= x <= 255 Use the next x - 128 + 1 bytes literally
(no repetition)

There are two kinds of *.SPS files.

The data may appear in the same order as *.SPC files (SPSLIDEX format?):

1. Picture data, bit plane 0, scan lines 1 - 199
2. Picture data, bit plane 1, scan lines 1 - 199
3. Picture data, bit plane 2, scan lines 1 - 199
4. Picture data, bit plane 3, scan lines 1 - 199

The second variant (ANISPEC format?) encodes the data as byte wide vertical
strips:

Picture data, bit plane 0, scan line 1, columns 0 - 7.
Picture data, bit plane 0, scan line 2, columns 0 - 7.
Picture data, bit plane 0, scan line 3, columns 0 - 7.
. . .
Picture data, bit plane 0, scan line 199, columns 0 - 7.
Picture data, bit plane 0, scan line 1, columns 8 - 15.

```
Picture data, bit plane 0, scan line 2, columns 8 - 15.
. . .
Picture data, bit plane 0, scan line 199, columns 312 - 319.
Picture data, bit plane 1, scan line 1, columns 0 - 7.
. . .
Picture data, bit plane 3, scan line 198, columns 312 - 319
Picture data, bit plane 3, scan line 199, columns 312 - 319.
```

A for loop to process that data would look like

```
for (plane = 0; plane < 4; plane++)
for (x = 0; x < 320; x += 8)
for (y = 1; y < 200; y++)
for (x1 = 0; x1 < 8; x1++)
image[y, x + x1] = ...
```

Color map compression:

Color map compression is similar to *.SPC color map compression, but the map is compressed as a string of bits, rather than words. There are 597 records (one for each palette). Each record is composed of a 14-bit header followed by a number of 9-bit palette entries. The 14-bit header specifies which palette entries follow (1 = included, 0 = not included). The most significant bit of the header refers to palette entry 1, while the least significant bit refers to palette 14. Palette entries 0 and 15 are forced to black (zero). Each palette entry is encoded as "rrrgggbbb".

The format of the palette is described above in the section on uncompressed Spectrum pictures (*.SPU).

<Art Director> *.ART (low resolution only)

```
16000 words picture data (screen memory)
16 words palette
15 * 16 words 15 more palettes for animation
-------------
32512 bytes total
```

<C.O.L.R. Object Editor Mural> *.MUR (low resolution only)

```
16000 words picture data (screen memory)
(palettes are stored in separate files)
-----------
32000 bytes total
```

<Doodle> *.DOO (high resolution only)

```
16000 words picture data (screen memory)
-----------
32000 bytes total
```

<Cyber Paint Sequence> *.SEQ (low resolution only)

This format, while fairly complex, yields excellent compression of animated images while offering reasonably fast decompression times.

```
1 word magic number [$FEDB or $FEDC]
1 word version number
1 long number of frames
1 word speed (high byte is vblanks per frame)
118 bytes reserved
---------
128 bytes total for .SEQ header

for each frame {
1 word type (ignored?)
1 word resolution [always 0]
16 words palette
12 bytes filename [usually " . "]
1 word color animation limits [not used]
1 word color animation speed and direction [not used]
1 word number of color steps [not used]
1 word x offset for this frame [0 - 319]
1 word y offset for this frame [0 - 199]
1 word width of this frame, in pixels (may be 0, see below)
1 word height of this frame, in pixels (may be 0, see below)
1 byte operation [0 = copy, 1 = exclusive or]
1 byte storage method [0 = uncompressed, 1 = compressed]
1 long length of data in bytes (if the data is compressed, this
will be the size of the compressed data BEFORE decompression)
60 bytes reserved
--------
128 bytes total for frame header

? bytes data
}
```

Frames are "delta-compressed," meaning that only the changes from one frame to the next are stored. On the ST, .SEQ files are always full-screen low resolution animations, so the sequence resulting from expanding all the data will be n 320 by 200 pixel low resolution screens, where n is given in the .SEQ header.

Since only the changes from frame to frame are stored, image data for a frame will rarely be 320x200 (except for the very first frame, which will always be a full screen). Instead what is stored is the smallest rectangular region on the screen that contains all the changes from the previous frame to the current frame. The x offset and y offset in the frame header determine where the upper left corner of the "change box" lies, and the width and height specify the box's size.

Additionally, each "change box" is stored in one of five ways. For each of these, the screen is assumed to have the full-screen image from the last frame on it.

o uncompressed copy: The data for this frame is uncompressed image data, and is simply copied onto the screen at position (x, y) specified in the frame header.

o uncompressed eor: The data for this frame is exclusive or'ed with the screen at position (x, y).

o compressed copy: The data for this frame must be decompressed (see below), and then copied onto the screen at position (x, y) specified in the frame header.

o compressed eor: The data for this frame must be decompressed (see below), and then exclusive or'ed with the screen RAM at position (x, y).

o null frame: The width and/or height of this frame is 0, so this frame is the same as the previous frame.

Of the 5 methods above, the one that results in the smallest amount of data being stored for a particular is used for that frame.

Compression Scheme:

Compression is similar to that employed by Tiny, but is not quite as space-efficient.

Control word meanings:

For a given control word, x:

x < 0 Absolute value specifies the number of unique words to take from the data section (from 1 to 32767).
x > 0 Specifies the number of times to repeat the next word taken from the data section (from 1 to 32767).

Note that a control word of 0 is possible but meaningless.

Format of expanded data:

The expanded data is not simply screen memory bitmap data; instead the four bitplanes are separated, and the data within each bitplane is presented vertically instead of horizontally. (This results in better compression.)

To clarify, data for a full screen would appear in the following order:

```
bitplane 0, word 0, scanline 0
bitplane 0, word 0, scanline 1
...
bitplane 0, word 0, scanline 199
bitplane 0, word 1, scanline 0
bitplane 0, word 1, scanline 1
...
bitplane 0, word 1, scanline 199
...
bitplane 0, word 79, scanline 199
bitplane 1, word 0, scanline 0
...
```

bitplane 3, word 79, scanline 199

Note however, that the data does not usually refer to an entire screen, but
rather to the smaller "change box," whose size is given in the frame header.

<Animatic Film> *.FLM (low resolution only)

1 word number of frames
16 words palette
1 word speed (0 - 99; value is 99 - # vblanks to delay between frames)
1 word direction (0 = forwards, 1 = backwards)
1 word end action (what to do after the last frame)
0 = pause, then repeat from beginning
1 = immediately repeat from beginning
2 = reverse (change direction)
1 word width of film in pixels
1 word height of film in pixels
1 word Animatic version number (major) [< 2]
1 word Animatic version number (minor)
1 long magic number 27182818 (hex)
3 longs reserved for expansion (should be all zeros)
----
32 words total for header

? words image data (words of screen memory) for each frame, in order

<Animaster Sprite Bank> *.ASB (low resolution only)

1 word number of frames - 1
1 word ?
1 byte maximum width, in pixels
1 byte maximum height, in pixels
16 words palette
----
38 bytes total for header

For each frame {
1 word width of this frame (in pixels) - 1
1 word height of this frame (in pixels) - 1
1 word ?
? words image data (words of screen memory)
}

<STOS> *.MBK

9 words ?
1 long $19861987 (magic number?)
1 long offset from this long to header for low resolution
parameter block (if past end of file, no low res frames)
1 long offset from this long to header for med resolution
parameter block (if past end of file, no med res frames)
1 long offset from this long to header for high resolution
parameter block (if past end of file, no high res frames)

```
1 word number of low resolution frames
1 word number of medium resolution frames
1 word number of high resolution frames

For each frame {
1 long offset to data (probably only used internally by STOS)
1 byte width in words (multiply by 16 to get width in pixels)
1 byte height in pixels
1 byte X hotspot location
1 byte Y hotspot location
}

(The format implies other stuff could be here.)

1 long ["PALT" $50414C54]
16 words palette

? words of data for each frame, in the order mentioned in the
header. Monoplanar mask data follows image data for each frame.
----------
? words total

The frames often seem to be in semi-random order, not necessarily in
the order they are to be animated.

<GEM Bit Image> *.IMG

1 word version number of image file [1]
1 word length of header in words [usually 8]
1 word number of color planes [1 for monochrome]
1 word pattern length in bytes [1-8, usually 2 for screen images]
1 word pixel width in microns (1/1000 mm, 25400 microns per inch)
1 word pixel height in microns
1 word line width in pixels
1 word number of lines
-------
? words header length defined in 2nd word of header

? bytes data

NOTES: If the image is a color image (planes > 1), the planes are stored
separately starting with plane 0. There is, however, no standard way of
storing the color palette. Some programs may save the palette in separate
files, some may extend the header. For this reason, you should never
assume the header is 8 words long, always get the header length from the
2nd word of the header. Also, the line width in the 7th word is the number
of pixels in a line. Since the data is encoded in byte-wide packets, the
actual unpacked line width is always a multiple of 8, and may be 1-7 pixels
longer than the length specified in the header.

For each byte x in the data section,

x = 0 Pattern/scanline run.
Read the next byte, n (unsigned).
```

If n > 0 then:
Read a number of bytes equal to the "pattern
length" word in the header. Repeat this
pattern n times.

If n = 0 then:
Scanline run. Data for the next scanline
is to be used multiple times. Read the
following record:

1 byte flag byte [$FF]
1 byte number of times to use
next scanline data

The data for the next scanline follows,
compressed normally.

x = 80 (hex) Uncompressed bit string. The next byte
determines the number of bytes to use
literally. The literal data bytes follow.

otherwise Solid run. The value of x determines
what to draw. The high bit specifies whether
the pixels are set or cleared. A 1 indicates
a byte-run using $FF, a 0 indicates a byte-run
using $00. The low 7 bits, taken as an unsigned
quantity, specify the length of the run in bytes.

<STAD> *.PAC (high resolution only)

4 bytes "pM86" (vertically packed) or "pM85" (horizontally packed)
1 byte id byte
1 byte pack byte (most frequently occuring byte in bitmap)
1 byte "special" byte
----
7 bytes total for header

? bytes data

The data is encoded as follows. For each byte x in the data section:

x = id byte Read one more byte, n. Use pack byte
n + 1 times.
x = "special" byte Read two more bytes, d, and n (in order).
Use byte d n times.
otherwise Use byte x literally.

<Imagic Film/Picture> *.IC1 (low resolution)
*.IC2 (medium resolution)
*.IC3 (high resolution)

4 bytes "IMDC"
1 word resolution (0 = low res, 1 = medium res, 2 = high res)
16 words palette
1 word date (GEMDOS format)

```
1 word time (GEMDOS format)
8 bytes name of base picture file (for delta compression), or zeroes
1 word length of data (?)
1 long registration number
8 bytes reserved
1 byte compressed? (0 = no, 1 = yes)

If compressed {
1 byte delta-compressed? (-1 = no, > -1 = yes)
1 byte ?
1 byte escape byte
}
-------
65 bytes total for header (68 bytes if compressed)

? bytes data

Compressed data may be either stand-alone or delta-compressed (relative
to the base picture named in the header). Delta compression involves
storing only how the picture differs from the base picture (i.e., only
portions of the screen that have changed are stored). This is used to
to encode animated sequences efficiently.

Compressed data, stand-alone:

For each byte x in the data section:

x = escape byte Read one more byte, n. (n is unsigned).

If n >= 2, use the next byte n times.
If n = 1, keep reading bytes until a
byte k not equal to 1 is encountered.
Then read the next byte d.
If the number of 1 bytes encountered is o,
use d (256 * o + k) times. I.e.,

if (n == 1) {
o = 0;
while (n == 1) {
o++;
n = next byte;
}

k = n;
d = next byte;

Use d (256 * o + k) times.
}
else {
d = next byte;
Use d (n) times.
}

x != escape byte Use x literally.
```

Compressed data, delta compressed:

For each byte x in the data section:

x = escape byte Read one more byte, n. (n is unsigned).

If n >= 3, use the next byte n times.
If n = 1, do the same as for n = 1 in
stand-alone compression (above).
If n = 2, then set n = next byte.
If n = 0, end of picture.
If n >= 2, take n bytes from base
picture.
If n = 1, do the same as for n = 1
in stand-alone compression (above),
but take (256 * o + k) bytes from
base picture.

x != escape byte Use x literally.

<IFF Format> *.IFF

4 bytes "FORM" (FORM chunk ID)
1 long length of file that follows
4 bytes "ILBM" (InterLeaved BitMap file ID)

4 bytes "BMHD" (BitMap HeaDer chunk ID)
1 long length of chunk [20]
20 bytes 1 word = image width in pixels
1 word = image height in lines
1 word = image x-offset [usually 0]
1 word = image y-offset [usually 0]
1 byte = # bitplanes
1 byte = mask (0=no, 1=impl., 2=transparent, 3=lasso)
1 byte = compressed [1] or uncompressed [0]
1 byte = unused [0]
1 word = transparent color (for mask=2)
1 byte = x-aspect [5=640x200, 10=320x200/640x400, 20=320x400]
1 byte = y-aspect [11]
1 word = page width (usually the same as image width)
1 word = page height (usually the same as image height)

4 bytes "CMAP" (ColorMAP chunk ID)
1 long length of chunk [3*n where n is the # colors]
3n bytes 3 bytes per RGB color. Each color value is a byte
and the actual color value is left-justified in the
byte such that the most significant bit of the value
is the MSB of the byte. (ie. a color value of 15 ($0F)
is stored as $F0) The bytes are stored in R,G,B order.

4 bytes "CRNG" (Color RaNGe chunk ID)
1 long length of chunk [8]
8 bytes 1 word = reserved [0]
1 word = animation speed (16384 = 60 steps per second)

1 word = active [1] or inactive [0]
1 byte = left/lower color animation limit
1 byte = right/upper color animation limit

4 bytes "CAMG" (Commodore AMiGa viewport mode chunk ID)
1 long length of chunk [4]
1 long viewport mode bits (bit 11 = HAM, bit 3 = interlaced)

4 bytes "BODY" (BODY chunk ID)
1 long length of chunk [# bytes of image data that follow]
? bytes actual image data

NOTES: Some of these chunks may not be present in every IFF file, and may not be in this order. You should always look for the ID bytes to find a certain chunk. All chunk IDs are followed by a long value that tells the size of the chunk (note that "ILBM" is not a chunk ID). This is the number of bytes that FOLLOW the 4 ID bytes and size longword. The exception to this is the FORM chunk. The size longword that follows the FORM ID is the size of the remainder of the file. The FORM chunk must always be the first chunk in an IFF file.

The R,G,B ranges of AMIGA and ST are different (AMIGA 0...15, ST 0...7), as is the maximum number of bitplanes (AMIGA: 5, ST: 4).

Format of body data

An expanded picture is simply a bitmap. The packing method is PackBits (see below), and is identical to MacPaint and DEGAS Elite compressed.

The (decompressed) body data appears in the following order:

line 1 plane 0 ... line 1 plane 1 ... ... line 1 plane m
[line 1 mask (if appropriate)]
line 2 plane 0 ... line 2 plane 1 ... ... line 2 plane m
[line 2 mask (if appropriate)]
...
line x plane 0 ... line x plane 1 ... ... line x plane m
[line x mask (if appropriate)]

The FORM chunk identifies the type of data:

"ILBM" = interleaved bit map
"8SVX" = 8-bit sample voice
"SMUS" = simple music score
"FTXT" = formatted text (Amiga)

<MacPaint> *.MAC

1 long version number [0=ignore header, 2=header valid]
38 * 8 bytes 8x8 brush/fill patterns. Each byte is a pattern row, and the bytes map the pattern rows top to bottom. The patterns are stored in the order they appear at the bottom of the MacPaint screen top to bottom, left to right.
204 bytes unused

```
-------------
512 bytes total for header

< 51200 bytes compressed bitmap data
-------------
< 51712 bytes total
```

NOTE: The version number is actually a flag to MacPaint to indicate if the brush/fill patterns are present in the file. If the version is 0, the default patterns are used. Therefore you can simply save a MacPaint file by writing a blank header (512 $00 bytes), followed by the packed image data.

Bitmap compression:

The bitmap data is for a 576 pixel by 720 pixel monochrome image. The packing method is PackBits (see below). There are 72 bytes per scan line. Each bit represents one pixel; 0 = white, 1 = black.

<RGB Intermediate Format> *.RGB (low resolution only)

This format was invented by Lars Michael to facilitate conversions between standard ST picture formats and higher resolution formats like GIF and IFF. It supports 12 bits of color resolution by keeping the red, green and blue components in separate bit planes.

```
1 word resolution (ignored)
16 word palette (ignored)
16000 words red plane (screen memory)
1 word resolution (ignored)
16 word palette (ignored)
16000 words green plane (screen memory)
1 word resolution (ignored)
16 word palette (ignored)
16000 words blue plane (screen memory)
------------
96102 bytes total
```

The format was derived by concatenating three DEGAS .PI1 files together -- one for each color gun. The RGB value for a pixel is constructed by looking at the appropriate pixel in the red plane, green plane, and blue plane. The bitplanes are in standard ST low resolution screen RAM format, but where pixel values in screen RAM refer to palette entries (0 through 15), pixel values here correspond to absolute R, G, and B values. The red, green, and blue components for each pixel range from 0 to 15 (4 bits), yielding a total of 12 bits of color information per pixel. Not coincidentally, this is exactly the format of ST palette entries (although on ST's without the extended palette only the lower 3 bits of each color component are used).

You can view a single bit plane on a standard ST by splitting the .RGB file into its three DEGAS .PI1 components and setting the palette to successively brighter shades of gray.

<ComputerEyes Raw Data Format> *.CE1 (low resolution)
*.CE2 (medium resolution)

1 long [$45594553 or "EYES"]
1 word resolution [0 = low res, 1 = medium res]
8 words ?
If resolution = 0 {
64000 bytes red plane, 320 x 200, 1 pixel per byte
64000 bytes green plane, 320 x 200, 1 pixel per byte
64000 bytes blue plane, 320 x 200, 1 pixel per byte

192022 bytes total
}
else If resolution = 1 {
128000 words 640 x 200, 1 pixel per word

256022 bytes total
}

This is almost two formats in one:

Low resolution:

The planes are arranged vertically, instead of horizontally.
The first byte is the red component of pixel (0,0), the second is (0,1),
and the third (0,2). The 201st corresponds to (1,0), etc. The 64001st
byte is the green component of (0,0).
Only the low six bits of each byte are used.

Medium resolution:

The picture is arranged vertically, instead of horizontally.
The first word is pixel (0,0), the second is (0,1), and the third
(0,2). The 200th is (1,0) etc.
Each word is divided up into the RGB values for the corresponding
pixel, as follows:

Bit: (MSB) 15 14 13 12 11 10 09 08 07 06 05 04 03 02 01 00 (LSB)
-- -- -- -- -- -- -- -- -- -- -- -- -- -- -- --
0 B4 B3 B2 B1 B0 G4 G3 G2 G1 G0 R4 R3 R2 R1 R0

Bit 15 is not used.

<PackBits Compression Algorithm>

The following packing algorithm originated on the Mac, was adopted by
Electronic Arts/Commodore for use in the IFF standard, and then by Tom
Hudson for use in DEGAS Elite. The algorithm is currently used in
MacPaint, IFF, and DEGAS Elite compressed file formats. Each scan line
is packed separately, and packing never extends beyond a scan line.

For a given control byte 'n':
0 <= n <= 127 : use the next n + 1 bytes literally (no repetition).
-127 <= n <= -1 : use the next byte -n + 1 times.
n = -128 : no operation, not used.

---

* Roland Waldi contributed extensive information on the following formats:

GEM, IMG, Doodle, STAD, Imagic Film/Picture, Art Director, IFF

** John Brochu, ST picture formats guru, provided sage advice and many corrections to the following formats:

NeoChrome, DEGAS Elite Compressed, Spectrum 512 Compressed,
GEM Bit Image, IFF, MacPaint

2794. Flickering B/W monitor

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-27 07:50:05 UTC
From: vic@sci.kun.nl
Message-ID: <vic.678009005@caligula>
Source record: 47734

Hi.
A couple of weeks ago my B/W monitor started to flicker. The size of the 'lit-up' part varied in size about 1 cm with a frequency of 1-4 Hz, and things are getting worse all the time. Sometimes there's an irregular shimmering too. These are all the symptoms. No extra (high frequent) noise, no ... Since I'm not afraid to handle a soldering iron, even with high voltage circuits, I'd like to have some ideas about what might be going on.
Thanx.

Most IDE drives for PC's are quite cheap these days. Can these drives be connected to the ST in any way? eg. IDE->ACSI or IDE->SCSI.

What sort of interface is IDE? Is it a low or high level one?

2796. HD appears sluggish

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-27 14:11:55 UTC
From: marc@sequoia.cray.com
Message-ID: <075027.10071@timbuk.cray.com>
Source record: 47737

Hi ST-people,

Now that I have my HD spinning away without zorching my video display [:-)]
I notice that writing to the HD is getting a bit sluggish. I was wondering why?

The drive is Toshiba, host adaptor is ICD. I run NeoDesk 2.0 on TOS 1.0 (yeah,
yeah, I know I ought to fit some new ROMs...). Setting write verify and cache
on or off makes no difference. Now, if I use ICD's RATEHD program, it tells me
the thing is shunting data at 589kB/s with a 25ms access time. That looks to me
to be FAST!!! So any clues why writing is a drag? Has the drive just become
monumentally fragmented?

Any help much appreciated. :-)

2797. Quantum Datapulse Hard Drives - any good ?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-27 15:03:54 UTC
From: cmp8157@sys.uea.ac.uk
Message-ID: <1291@sys.uea.ac.uk>
Source record: 47735

I'm just about to (at very long last) get a TT and instead of the
normal hard drive I'm having a 105Mb Quantum Datapulse (as used by the US
military or so the shop tells me) installed instead. I was just wondering
whether anybody has had any problems using one with an ST or TT. It may
get occassionally attached to my ST (which I can't bear to part with as I
want to keep all my games) so the ST part is important.
As well as problems I also wouldn't mind any other comments such as
"Yes it's very nice... it's completely silent, hardly uses any electric,
never crashes" (maybe a bit of wishful thinking there :-)) or "I've used
6 different hard drives and compared to all the others it's..."

Please EMAIL any comments on these drives to:

cmp8157@sys.uea.ac.uk

Thanks in advance (assuming anybody bother to reply),

Steve Sowerby B.Sc.(Hons) - I've just got my degree (WAHAAY!!!)
School of Information Systems, and I don't care if I haven't actually
University of East Anglia, graduated yet!!! :-)
Norwich, England.

2798. Re: 1024-byte floppy sectors?

In article <2969@atari.UUCP>, apratt@atari.UUCP (Allan Pratt) says:
>
>Roger.Sheppard@actrix.gen.nz (Roger Sheppard) writes:
>>> ...and hard-disk partitions larger than
>>> 16MB are implemented using large logical sectors...
>> ^^^^
>>Correct me if I am wrong, but should this not read 32MB ?, I thought
>>that this was a typo that caused this problem and was fixed in TOS 1.4
>
>It may or may not have been fixed, but because even people with TOS 1.2 and
>(gasp!) TOS 1.0 want to be able to use large partitions, HDX goes to BGM at
>16MB for maximum compatibility. Otherwise you could take a 31MB, non-BGM
>partitioned disk to a machine running TOS 1.2 and not be able to get at
>the files.
>
But I really would like to know, whether such partitions DO work under TOS 1.04
(GEMDOS 0.15). I think they do, but how can I be sure?
Reason: my harddisk partitioning utility automatically switches to larger
sectors (and BGM) for partitions larger than 16 MB. But when manually editing
partition and sector sizes, it allows for 32MB partitions with 512 byte
sectors (warning, that these partitions can't be used under old GEMDOS
versions).
Is this behaviour tolerable, or should I remove this 'feature'?

2803. Microsoft Mouse (Variation on FAQ)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-28 08:52:40 UTC
From: neil@cs.hw.ac.uk
Message-ID: <3323@odin.cs.hw.ac.uk>
Source record: 47644

I had a look at a Microsoft compatible mouse yesterday and since it plugs into a PC serial port I thought why not bung it in an ST serial port. I checked the wiring first and it uses GND, TX, RX and RTS (for power).

Sure enough. Wiggling the mouse while running Uniterm gave loads of garbage on the screen. So the questions are:-

* What is the correct BAUD rate?
(I was getting 'reasonable' garbage at 1200)

* How may databits and stopbits?

* What does the 'garbage' mean?

If I get good answers to the above then I'll write a driver to replace the standard mouse with the MS Mouse and/or support two mice.

Why am I doing this? Well I just thought it might be fun to have two mice on one machine. I might even write a weird game to use them. Two player Missile Command anyone?

Neil

p> someone tell me if there is a bug with Microsoft Write's print
p> Metafile option? (I have a utility to convert a Metafile to
p> postscript, but I always get a metafile corruption error.
p> Unfortunately, I do not know whether it is a problem with the utility
p> or Write and I do not have another application that generates
p> metafiles!). Thank you in advance.

The 'mfps' utility by Axel Mahler only treats Metafiles with some conventions,
such as the ones created by GemDraw or EasyDraw : for instance, the 'metafile
extents' *must* be set, and there are other restrictions.

A possibility would consist in printing the Metafile with the old OUTPUT.APP
with a GDOS PostScript driver (it exists, but I don't remember where I've seen
it). Let me know if it works.

2806. getting TeX up and running on your ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-28 15:58:06 UTC
From: davidli@simvax.labmed.umn.edu
Message-ID: <1991Jun28.155806.1@simvax.labmed.umn.edu>
Source record: 47645
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

Basic Installation of a working TeX/LaTeX on an Atari ST.

The following is a description of what I did in order to install TeX and LaTeX on my Mega4 ST with a 20 megabyte hard drive and an Epson LX-86 printer, using files available on the atari.archive.umich.edu server. The basic system described occupies a bit over 4 megabytes on my 'd:\' partition, and I still need more fonts ...

WARNING
=======

If you don't have more than 1 megabyte of memory, you'll need one of the special shells available in /atari/tex/shells. Otherwise, GULAM or MUPFEL or OKAMI might work just swell. And don't even think about running undump.ttp on anything less than a 2.5 meg machine. The following is informational ... don't blame me if you become a TeX addict.

Some setup stuff
================

Directory structure:

\tex
\tex\fonts
\tex\formats
\tex\inputs

Environmental variables:

TEXFONTS \tex\fonts
TEXFORMATS \tex\formats
TEXINPUTS \tex\inputs
TEXPOOL \tex

Files used in installation (all are available from atari.archive.umich.edu):

TEXBIN.LZH INPUTS.LZH TFMFONTS.LZH BIBTEX.LZH
FORMAT31.LZH MANPAGES.LZH DVIFNTS1.ZOO DVIFNTS2.ZOO
DVIFNTS.HLP DVIATARI.ZOO DVIEPS.ZOO

"How I did it"
==============

1. Unarchive MANPAGES.LZH and place the files where you usually keep man pages. (I put them in \usr\man\man1)

2. Unarchive the fonts files DVIFNTS1.ZOO and DVIFNTS2.ZOO.

```
cd \
zoo -restore dvifnts1
zoo -restore dvifnts2
```

Notes: The commands above restore the fonts in a root directory '\fonts'. Use whatever methods you have (I used UIS 3) to move the directories under '\fonts' to \tex\fonts.

3. Unarchive TEXBIN.LZH and place the files in \tex.

4. Unarchive BIBTEX.LZH and place the files in \tex.

5. Unarchive INPUTS.LZH and place the files in \tex\inputs.

Notes: There are some longer-than-8-character file names in the archive. Fortunately, they're all first-8-character-unique.

6. Unarchive FORMAT31.LZH and place the files in \tex\formats.

7. Unarchive TFMFONTS.LZH and place the files in \tex\fonts.

Notes: There are some longer-than-8-character file names in the archive. Unfortunately, several of these are NOT first-8-character-unique. I did nothing beyond answering 'no' to LHarc queries about overwriting files. The long file names appear to be present in a shorter form as well -- and they're all PostScript font names anyway...

8. Unarchive DVIATARI.ZOO and place the files in \tex.

9. Unarchive DVIEPS.ZOO. You only need the following files from the archive:

DVIE72.TTP DVIEPS.TTP EPS.TTP SETUPTEX.G

Notes: Some 'nice to have' files include: README.TEX and DVIST.DVI. Most of the files in this archive are source code, and you don't really need them to make the TeX and LaTeX work.

10. Set the environmental variables. There is a gulam script called SETUPTEX.G works quite nicely once you've edited it to reflect proper disk partitions (ignore the aliases though).

11. Test the setup using README.TEX from the DVIEPS.ZOO archive:

```
cd \tex
virtex \&lplain readme.tex
dviatari readme
dvieps -z readme
```

Notes: The gulam CLI requires the '\' before the '&' -- the CLI I use works nicely with 'virtex &lplain'. HOWEVER, LaTeX was unable to find the file 'readme.tex', and I had to enter the filename at the prompt as '.\readme.tex'. If anyone has any idea why this might be, please let me know. It -might- be because of ARGV vs. xARG problems...

dviatari.ttp worked nicely on my color monitor, although it had to substitute some 300dpi fonts because I was missing 240dvi fonts, so

some things look a little funny.

dvieps.ttp worked nicely for my Epson LX-86 9-pin printer. It takes
a looooooong time to print, though the output is truly 'TeX' standard.
Without the '-z', a file will be created -- but beware! The file takes
about 350K disk space per page!!

OK, so what next?
==========

There are other device drivers, including PostScript and HP Deskjet drivers
available. I don't have anything to test these with (yet... I just got the
GhostScript drivers.)

There is a definite need for more 1200 magnification (240dpi) fonts, since
both dviatari.ttp and dvieps.ttp use this magnification of fonts. So, it
looks like I'll have to get hold of MetaFont and spend some time creating
more fonts.

I tried using the 'undump' program, also available on atari.archive.umn.edu.
It produced an 850K LaTeX executable. I decided that virtex.ttp and the
lplain.fmt file were fine, since they didn't take up 850K together. and
to produce executables for TeX, LaTeX and SliTeX would take up nearly 2.5
megabytes of space on my 20 meg hard disk.

I also ran a LaTeX file called 'layout.tex' through, and it produced very
nice output, although the fonts were off because they were 300dpi rather
than 240dpi.

There are, of course, more files in the /atari/tex/tex31 directory, but they're
not necessary for a basic working system (ie. nice to have, so if you have
the disk space, unarchive them in your \tex directory). By the way, just what
is VF_FONTS.LZH useful for anyway???

Oh yes ... don't bother with the other font archives in the directory
/atari/tex/fonts on the atari.archive.umich.edu server. They don't contain
any =different= fonts from those in the two Zoo archives mentioned above.

Fonts. Did I mention fonts?

That's all folks
==========

I hope this helps someone out there who's been dying to try TeX and LaTeX
but couldn't figure out what was needed to set up a workable system.

Please feel free to write to me with your experiences, advice on getting
more 240dpi fonts, alternative methods of putting things together, etc.

2807. Mono monitor blacking

Newsgroup: comp.sys.atari.st.tech
Date: 1991-06-29 19:54:08 UTC
From: JJL101@psuvm.psu.edu
Message-ID: <91180.155408JJL101@psuvm.psu.edu>
Source record: 47650

Previously I had thought that this problem I was having with my monitor
was due to interference although now I am not too sure. Here are the
symptoms:
Often when I turn the monitor on after a period of non-use the screen
is almost completely black. Any letters on the screen though are somewhat
visible but in an inverse shadowed kind of way. Then the longer it remains
on the blackness seems to dissappear, into vertical bands of horizontal
lines like this across the screen

```
== == == ===
== == == ===
== == == ===
== == == ===
== == == ===
== == == ===
```

These lines fade in and out a lot until after a period of time.

Does any one have any ideas on this?

J.J.

Howdy - could someone please remind me where to get an adapter for fitting a standard DIP 68000 into the socket in an STe? (Not a Mega STe, if it matters.)

Also, a while ago, someone mentioned seeing a board for sale that adapted a 68020+FPU to run in a 68000 socket. I contacted the company, and found that they make accelerators for Amigas. The 68020 product uses a 12MHz 020 running off the standard system clock (e.g., 8MHz in ST) and an FPU running as fast as you want, up to 50MHz.

I didn't get a price on this item... However, they sell other models of accelerators - I've ordered a 25MHz 68030 for $600, to test in my STe. It would be great if I could run it at 16 or 32MHz, but I guess I'm just going to see if it runs at 8 first. Should be interesting.

Does anybody know where to find a screen dumper (hooks $502 or $506 or something like that) that will work with an Okidata OL-400? The manuals say its command language is HP-PCL, so a HP LJ-II screen dumper ought to work.

Thanks in advance.

I've observed the following incompatible things about using overscan.
I'd like to know if anybody has fixes or work-arounds for them:

1. The VT52 emulator (the one used for .TOS and .TTP programs) doesn't
scroll correctly. Once the screen fills, it just copies the bottom line
forevermore.
2. If I setup a desktop.inf to make my windows tall, and put some icons
(e.g. trash) far down the screen, and then re-boot with overscan off, the
icons are all on the screen, but the windows aren't. In particular, the
size box is off-screen. One CAN re-size by making the windows FULL, and then
dragging to the right size, but it would be easier if the desktop just made
sure it's windows would fit when they're opened.
3. TrboDemo crashes the system.
4. v_clrwk doesn't clear all the screen, and it somehow mahes what it DOES
clear jitter (a lot).
5. Uniterm doesn't work :-(.
6. OSCAN_60 doesn't let me run in either low or medium rez. The first
setup screen seems OK, the second (with the lines around and across the
screen) is a little screwy (the diagonal lines are triple, in different
colors), and when I finish setup, I've got hash. I'm using the one
called 1.6b. I forgot who "improved" it.

Other stuff I'm using includes:
VDIFIX version 30.01.91
PoolFix3, improved by Claus Brod, 27 Mar 90
Foldr 100.

Thanks in advance for any advice.

This is an error in the OS. Scrolling only works if the bytes per line value diveded by 16 does not give a remainder. With the new AutoSwitch-Overscan the bytes per line value is 96 in mono or 224 in the color resolutions, so there is no scrolling problem.

>2. If I setup a desktop.inf to make my windows tall, and put some icons

>sure it's windows would fit when they're opened.

This again is a problem of the OS. It was fixed in the new TOS-version. You get the same problems, if you save your Desktop.Inf in high-res and reboot in low-res.

>3. TrboDemo crashes the system.

If you mean a demo of TurboST, then you are right. TurboST does not work with overscan. QuickST works, but has some problems with the TOS scrolling (fillding with the right black border). Darek is working on it (I hope so ;-). The NVDI software has no problems with OverScan or AutoSwitch-OverScan.

>4. v_clrwk doesn't clear all the screen, and it somehow mahes what it DOES
>clear jitter (a lot).

This is a very old bug, that is fixed in the autoswitch-OverScan driver. There were about 52 versions between the old PD/ShareWare version of OverScan and the new driver.

>5. Uniterm doesn't work :-(.

AutoSwitch-OverScan switches back to the normal screen, if you start incompatible programs. So you can use lots of 'old' software that did not work with the overscan mod.

>6. OSCAN_60 doesn't let me run in either low or medium rez. The first
>setup screen seems OK, the second (with the lines around and across the

The autoswitch-OverScan driver works in all resolutions.

>Other stuff I'm using includes:
>VDIFIX version 30.01.91
>PoolFix3, improved by Claus Brod, 27 Mar 90
>Foldr 100.

The driver includes most of my patches (VdiFix, Tos14Fx5, GemEnv, Shell0,
ConsFix), so you don't have to load them in the auto-folder. If you don't
want the patches, you can disable them.

AutoSwitch-OverScan will be available in the US in the near future, we
have already contaced some dealers for the distribution. In the UK you
can by AS-OverScan at Atari Workshop.

>Thanks in advance for any advice.

I could not give you any direct hint how to get rid of your problems, but
i hope i explained why the things happen in this way...

Hi Mark,
Well I would say that the major reason that the "writes" are so
slow on your hard drive has to do with you still using TOS 1.0. TOS 1.04 (1.4)
would make a big difference. If you cannot afford to upgrade to TOS 1.04, put
FATSPEED.PRG in the AUTO folder of your boot drive (FATSPEED should be first in
the AUTO folder, even before PINHEAD.PRG). Bye.................

Luis

2814. Re: 1024-byte floppy sectors?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-01 17:17:43 UTC
From: pegram@kira.UUCP
Message-ID: <1991Jul1.171743.6611@uvm.edu>
Source record: 47654

Alan Pratt sez:
>>It may or may not have been fixed ... [the 512K sector, 32MB
partition bug. RBPIII]

If it isn't, the bug is *REALLY* RARE with TOS 1.4 and up. The ICD
formatter for my previous HA allowed 32Meg 512Byte sector partitions
once I got Tos 1.4. I never lost data for any unexplained reasons
(only because of my own error, just once I believe).

> But I really would like to know, whether such partitions DO work under TOS 1.04
> (GEMDOS 0.15). I think they do, but how can I be sure?
> Reason: my harddisk partitioning utility automatically switches to larger
> sectors (and BGM) for partitions larger than 16 MB. But when manually editing
> partition and sector sizes, it allows for 32MB partitions with 512 byte
> sectors (warning, that these partitions can't be used under old GEMDOS
> versions).
> Is this behaviour tolerable, or should I remove this 'feature'?
>
> _____________________________ cut here _____________________________________
> Julian F. Reschke, Hensenstr. 142, D-4400 Muenster, Phone: ++49 251 861241
> fast eMail: ONM07@DMSWWU1A.BITNET, slow: jr@ms.maus.de (++49 251 77216)
> _____________________ correct me if I'm wrong ______________________________

Question:

vvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvvv

How can I get a hold of your hard disk partitioning utility, or
something similar?

Can I get and use the Supra formatter/partitioner? Would it work with
a non-Supra adaptor? ICD software *only* works with ICD HAs.

I want 32Megabyte GEM partitions (*not* BGM), Tos 1.0 compatibility be darned!

^^^

Now that I have a BMS 200 Host Adaptor running my Seagate 296N, with
AHDI talking to it, I can't use Diamond Cache on the BGM partitions,
and could use the extra space that small sectors make available. I
had too many small files to restore, and the 32M BGM partition filled
before I reached the 29 - 30 MB that I had in the old 32M ICD partition.
That's at least proof that the ICD partition *was* using 512 byte
sectors.

Oh yeah, the BMS ads are for real, ICD's RateHd now says that I get
682KB/sec with my 1-1 interleaved 296N, rather than the ~420 -

430KB/sec I got with the old ICD adaptor, running the 296N in 2-1 interleave. That's one in the eye for that annoying ICD tech who told me that there was nothing wrong with their HA, just "some 2XXNs can run with 1-1 interleave and others can't". Wrong! BMS handles these admittedly ancient drives better than ICD, and ICD won't admit it (or at least not that guy)! BTW, your mileage may vary, my 296N is ~1.5 years old, certain versions may not runn at 1-1 interleave at all.

One gripe with BMS: The instructions for setting up with AHDI >= 3.01 is sketchy at best and many embedded SCSI drives will need extra formatting software to be formatted/partitioned correctly.
Otherwise, except for the built in cacheing and the much missed error checking and display, I'm quite happy with my new setup. The shoebox is as loud as my old box, but the mechanical-electrical work is first rate.

Hope someone can answer this,
Cheers,

Bob Pegram

2815. Atari Japan is on the move.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-02 08:30:56 UTC
From: ytsuji@wucc.waseda.ac.jp
Message-ID: <5955@wucc.waseda.ac.jp>
Source record: 47655

This is one of my farewell messages to my dearest Atari ST community.
I am very, very sorry that I have had to sell all my Atari lot and leave this community. Not that I have been unhappy with Atari, but I just could not afford to place two computers on my desk and Atari had to go.

Surprises come at the last moment, indeed! As soon as I posted a 'for sale' to Junet (kind of local internet in Japan, like Janet in UK), I had a great response and within two days the whole lot have gone! There are certainly people who would like to use Atari as a Post Script machine (mega4+slm804+ emulator), a GNU machine (mega4 + 66 mb disk), or as a simple vt102 terminal (UniTerm). I sold the whole lot (mega4,one internal high density drive, one external high density drive, an ICD SCSI adaptor, 50-pin ribbon cable connector to 50-pin Amphenol connector, an SM124 monitor, a megafile30 with 65 MB NEC disk inside, SLM804 laser printer, plus all the software I had) for US$1,500. This has enabled me to buy 20 megabytes of 80-ns SIMMs and ten QIC150 tapes for my new machine. So far a rather sad story.

The thing is that I just had a call from a gentleman who wished to buy the lot. Sorry, they are gone, but may I ask what you are interested in? The gentleman told me he is porting ATARI ST to the Japanese language environ-ment! Yes, Atari Japan is on the move. It's not sitting here viewing Apple taking advantage of the horrible quality of Japanese software market.
He said the low-end Amiga cannot print Japanese character on the screen due to poor resolution, but Atari's 640x400 was so easy to cope with.

Let's hope that I might be seeing Calamus handling Japanese characters soon.

There's actually a superb Japanese language front end processor in the public domain, which I am using now on my new machine. It is called Wnn and is better than any other front end processor (Japanese characters are an array of 16 bit code) available for less than US$7,000. Unfortunately mega4 could not compile Wnn because of the limited memory. And moreover, it is designed to be run in X window environment as well. X is again PD, but again mega4 cannot cope with it.

I'll be buying an Atari if I could have a larger house (which costs at least US$2,000,000!).

Bye.
Tsuji

P.S.
I might be popping in to my old friends. Till then, good bye.

2816. GAL 1.44M hack...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-02 11:26:34 UTC
From: yonder@netcom.COM
Message-ID: <1991Jul2.112634.18259@netcom.COM>

I am very intrigued by the GAL hack that was posted here. I must admit that my experience with GALs (and PALs) for that matter are not what they should be.

The GAL hack uses a 16V8-25 GAL. I have a friend who has a PAL programmer. I don't have any programmable logic databooks, so I stopped by a local electronics shop today that keeps a collection of books handy. Looking thru this book very quickly (I didn't have much time) I got the idea that the GAL can emulate on of several PAL's. Would it be possible to use an equivalent PAL for the GAL in this hack? Both the GAL & PAL sections of the databook meantioned that programmers use Jedec files (included with the hack).

My Q: If it is possible to use a PAL for the GAL, which one will work.
My Q2: Assuming it is possible to use a PAL, which PAL?
My Q3: Will the GAL Jedec file (included with the text file) work with the PAL. My friend said that he could not use the Jedec file and that he needed the "source" file. He meantioned an equivalent "fuse map". From what I remember from school, programming PALs is usually done by setting up logic statements relating the inputs to the outputs. Then the file is compiled into a fuse map and the PAL is programmed. Where does the Jedec file fit into this.

thanks......

HELP!

I just hooked up a Mitsumi 1.44MB drive to my ST. Now, if haven't fixed the controller yet to format 1.44MB's, but that isn't the problem.

It seems that my ST thinks both Drive A and B exist even though I only have one drive! What ever do I do to fix this? Also, I've gotten bombs when trying to delete stuff on a write protected disk. I think something is afoot!

The drive works otherwise. Please help me.

Dom

P.S. Has anybody seen or heard of a program that'll let you selectively turn on or off Drive B? i.e. you forgot to turn on Drive B and powerup, so you need to let the ST know it exists, or you are having problems with Drive B so you want the ST to think it isn't there.

Hi,

I have seen (in the UK) the Electrohome ECM11311 multisync monitor for sale
at a price of 149UKP.

Can anyone tell me anything about this monitor, and especially if it will
work in all three ST graphics modes.

I'm also thinking of getting an NEC 3D but this Electrohome monitor offer is
much cheaper, so I'd like to go for it if someone can tell me it will
work.

Thanks,
Paul

2822. Help with altboot4.0e

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-02 20:15:18 UTC
From: Bryan_Jones_Woodworth@cup.portal.com
Message-ID: <43907@cup.portal.com>
Source record: 47663
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I need HELP with Altboot 4.0e.

If you know what this program is (it lets you boot alternate configurations when you hold down ALTERNATE) then please attempt to assist me.

When executing my configuration files, all works well until I try to add a modifier for another type of file. Ex: To load a different desktop.inf, you enter a single-digit, such as "0" or "1" followed by return. ALTBT will then rename DESKTOP.IN0 to DESKTOP.INF and the previous DESKTOP.INF will have been renamed to what it was previously (DESKTOP.IN1 or some other).

I cannot get it to do this with a list of data (FILE.LST). This data file tells my Ramdisk copier what files to copy to Ramdisk upon bootup. I maintain many lists of FILE.LST (so they will give me flexibility with this programme). One will go with a 52K configured RAMdisk and copy UUD/UUE to RAM. another FILE.LST copies GIF viewers to RAM.

Here is an example of a configuration file which works.

```
hd_reset.prg enable hdreset
hdstrt10.prg Pick progs from a menu
codekeys.prg Install codekeys
lgselect.prx Don't want a file selector now
1 desktop.in1 = current desktop.inf
codekeys.acc Make codekeys work too
```

Now, according to the documentation, I should enter a "#" on an empty line; then the files with their path in order to rename 'em. So, I add:

```
#
a \ file.lst 1 file.ls1 will be current file.lst
```

However -- With these two additional lines, Alt-Boot ignores my configuration file completely. EXCEPT for the fact that it *does* say, "FILE.LS1 current FILE.LST" That is, it does *not* modify my programs/accs as specified in the beginning of the configuration file.

HELP!!!!

Any comments?
(I tried sending mail to author via Internet but frigger mail bounced)

I'm running Xcontrol and TOS14FIX without difficulties on an old 520,
TOS 1.04, monochrome.

I removed the window colors, sound and mouse accelerator CPX files. Did
you try that?

Steve Yelvington <steve@thelake.mn.org>

Try to get TOS14FX5 (this is not an official atari patch, it was written by
Karsten Isakiovic). There's a small typo with TOS14FIX.PRG (RTE instead of
RTS), that has been fixed in TSO14FX5...

Hmmm ... it doesn't seem to happen with me. Some differences might be
that I have an STe (TOS 1.6) and TOS14FX5. It stands for 'fix 5' of
TOS 1.4 fix and apparently it is an update. You can get it from
atari.archive under 'utilities/tosfixes/tos14fx5.lzh' - sounds like
it's worth a try.

>My Q: If it is possible to use a PAL for the GAL, which one will work.

GALs are more flexible with regard to pin-out, it is possible to use
a 20V8 GAL for every 24pin PAL, and a 16V8 for every 20 pin PAL. The
GALs accept the PAL JEDEC files (assuming a good programmer, smart
enough to understand this all; our DataIO Unisite does just fine)
The other way around, using a PAL for a GAL is more difficult, one could
imagine a strange GAL pinout (using the aformentioned flexibility) for which
there is no equivalent PAL.

>My Q2: Assuming it is possible to use a PAL, which PAL?
See above, this depends...

>My Q3: Will the GAL Jedec file (included with the text file) work with the
>PAL. My friend said that he could not use the Jedec file and that he

>Jedec file fit into this.

Normally the JEDEC file is produced by some sort of logic synthesis program
like ABEL (from DataIO) or PALASM. The JEDEC file is used by the actual
programmer to program the device. Since GALs emulate PALs on JEDEC file
level, but not the other way around, you cannot use the JEDEC file directly.
There are tools (for instance included in the ABEL package) who can convert
JEDEC back to ABEL or PALASM source or to fusemaps.

If you send me the JEDEC file, I can try to convert it back to source form
for you.

>
> I've been wondering about this too. I'd also like to see it, email it
> if neccessary.

On atari.archive.umich.edu is this file:
languages/sozoinit.zoo

I think this contains a Sozobon C startup module that will detect whether it is a program or a desk accessory. (If this is not the correct file, let me know and I'll do some rooting around.)

Bruce also asked about including a resource in the program. Some resource editors will produce a .C file, but the one I use doesn't, so I am grateful to Bob Silliker for RSC2C.TTP, which does the trick nicely.

programming/rsc2c1.arc contains the binary
programming/rsc2c2.arc contains the source code

The twitterpater binaries index includes
volume13/rsctoasm Convert .RSC files to assembly source

On Delphi, I've seen references to including resource files in GFA BASIC programs, but I don't do BASIC, so I didn't pay much attention.

A while ago i purchased an SM125 b/w monitor for only 150DM (about 85$, it was determined for use in UK), but w/o any warranty. As i connected it to my good old 1040, i realized that the missing warranty for this thing had a reason:

Nothing appeared on the screeeeeeeeEEEEEEEEEN :-(:-(:-(

After examining the monitor, i found the line transformer (i hope this is the right word; i mean the high voltage transf. for the CRT) defect. I contacted a few adresses i knew here in Germany and tried to get this essential part but had no success. :-(again

Now my question/request/entreaty/prayer/supplication to you:

- Does anybody know where i can get this transformer? It's really urgent!!!
- What does this thing cost???
- Can anybody provide adresses of MAIL orders which sell this thing???
- Could anybody possibly be so kind and purchase this thing and send it to me to Germany????

PLEASE HELP ME!!!!!!!!!!!!!!!!!!!!

Thanx
Juergen

2829. CITIZEN 1.44 drive

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-03 11:41:34 UTC
From: hb9zz@bernina.ethz.ch
Message-ID: <1991Jul3.114134.20572@bernina.ethz.ch>
Source record: 47668

I bought a CITIZEN drive to use with the HD 16MHz hack. The drive works
fine, and can read and write discs at 1.44 Mb. THe only problem is that
have to switch the clock per hand since I can't get the drive to output
the HD signal on the SASI bus. Does somebody have a solution to this
problem (ie. jumper setting, alternate output pin instead of 2...)

Ok, thanks in advance for the help

Ciao --- Rick

I have had a BMS-200 since they came out - has worked flawlessly for me, and BMS' support has been excellent, though they admittedly don't have system software for it. I've used the Supra utilities (available at most ST software stores, or direct from Supra, ~$25) and they work very well, including the ability to use large and/or >4 partitions.

Frankly, I'm amazed at how much people rave about the ICD software - it seems that an inordinately large number of incompatibilities with various software seems to be from the ICD driver (cacheing, etc.). I've _never_ seen the Supra software as the cause of an incompatibility, and I can't imagine that the ICD extras can't be equally well achieved by use of Cold Hard Cache, folderxxx.prg, etc. I don't mean to flame the ICD software, I'd just like to hear what makes it better.

2834. ST interfacing

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-03 18:38:17 UTC
From: todd@NISC.SRI.COM
Message-ID: <30455@fs2.NISC.SRI.COM>
Source record: 47671

I would like to interface some breadboarded circuits to my 1040ST.
Looking over "ST Internals" I see that I can't use the cartridge slot
or the printer port, but looks like the DMA port is the only way to go.
Does anyone have some advice or good detailed explanation of using
the DMA port to interface an arbitrary device? The stuff I want to build
will not need to do DMA transfers asynchronously from the CPU, but rather
the CPU can do the transfer when the device signals an interrupt, if that
makes the interfacing easier.

Todd Koumrian

No, I confess I didn't. I just killed off the AUTO folder and it worked.
I then went through the AUTO folder 1 PRG at a time until I found the culprit.
I was quite surprised. I have since been told of TOS14FX2 (Atari US) and
TOS14FX5 (Germany). Both of which I will try ASAP.

>atari.archive under 'utilities/tosfixes/tos14fx5.lzh' - sounds like
>it's worth a try.

You should have mentioned that TOS14FX5 is not an original ATARI patch
program. I send my bug report to ATARI about 2 years ago, but there was
no reaction. Nowadays, the communication to ATARI is much better and
bug reports realy reach the developer.

Here is what happens: In TOS14FIX there is a 'heavy' bug in the Rsconf()
routine. If you ask for the baud rate, the trap handler terminates with
RTS instead of RTE.

I fixed it (also used the XBRA standard...) and put it out as TOS14FX2 up to
TOS14FX5. Now that XCONTROL is PD, ATARI themself reacted to the bug-report
and made a new TOS14FIX, also called TOS14FX2. I think you should get this
one, since it is an official patch! I already changed the name of my version
to T14FIX5, to avoid confusion with the official TOS14FX2.

>>Bummer! I want both so when is the fix comin' out?

ATARI already put out the TOS14FX2.PRG as i already mentioned.

Sincerly, Karsten Isakovic <ki@opal.cs.tu-berlin.de>

2837. Problem w/ TeX 3.1 at atari.archive (was Re: getting TeX up and running on your ST)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-04 16:51:58 UTC
From: ralph@laas.fr
Message-ID: <RALPH.91Jul4185158@orion.laas.fr>
Source record: 47675
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

First of all, it is true that with the new TeX 3.1, undump would
probably not run on a 1040 since the undumped file is approx. 800 Kb!!
(as David Paschall-Zimbel stated). The older Tex 2.9, I was able to
undump on my old 1040 ST and it produced something a lot smaller.
[That's for information only.]

A related question: has anyone ported BigTeX to the ST? I use the
above undumped LaTeX and it blows up since I exhaust TeX's pool!!

Now to the problem that prompted this posting: it seems that TeX and
BibTeX under the TeX 3.1 directory at atari.archive use incompatible
TEXINPUTS environment variables. For TeX/LaTeX, concerning my
application, I need the following:

```
setenv TEXINPUTS '.\acm;.;e:\tex\inputs\local;e:\tex\inputs'
```

But unfortunately BibTeX requires this to be translated to emacs'
style:

```
setenv TEXINPUTS './acm:.:/dev/E/tex/inputs/local:/dev/E/tex/inputs'
```

I would appreciate BibTeX being re-uploaded to a.a if it would use the
more std. (this is only an opinion!) TeX/LaTeX style of paths. If it
would accept both, so much the better.

I do not see why the above configuaration should be more difficult
than the original port of GNU emacs to the ST. From the latter I have
learned that it is not easy to `dumpfix' ordinary xemacs. I suggest
to Erling Henanger to save 2 emacs images from say the gulam shell:
save one, then do a recursive call of gulam and then save the second.
Then dumpfix should work, or so I would think. This advice was sent
to me by Edgar Roeder at a time (quite some time ago) when he was more
talkative on the net.

Yesterday, I discovered that maccel3, the mouse-accelerator of atari, which saves the configuration in its program-file, uses Fopen with the mode readonly to open that file and writes then the data via Fwrite into it. Is that the correct way???? And why is there no error returned by GemDos?

BTW, if atari fixes this, they can do two more things: use the XBRA-method (maybe the do in maccel3, but I dont remember at the moment) and give maccel a cookie-name in ASCII, so that one can read it.

Nope, that's not the correct way. GemDos doesn't care about it and fixes this
internally, KAOS won't accept it...

Some networks also can be crashed with this. They just check for read/write
permissions when *opening* the file. If you have read-only access, open the
file for reading (correct so far) and write something into it, some programs
(PAMs Net... :-) won't recognize it.

Even worse: You can manipulate files marked as read-only if you just open
'em for reading and then write...

BTW: Are you allowed to change the date/time stamp with Fdatime() when
you open a file just for reading? GEMDOS allows it, but is it logically
correct?

I grabbed all 29 parts of the GNU emacs archive. I can't get it to work. It says in the "read_me" file that the termcap library is used, and that a sample file is included. I didn't see one!

I logged onto Genie, pulled the TERMCAP archive, and it has a TERMCAP file in it. It seems to define "st52" and "st52l" (50 lines). I tried setting the TERM environmental to st52, but it still complains that st52 is not powerful enough to run emacs, and it lacks the ability to move the cursor.

It hasn't been a fun Saturday! If anyone knows how to get this working I'd love some help!

Thanks!

John

2846. Determining available font sizes

the size of the undumped executable depends on the
configuration you use to compile TeX to size the arrays. for TeX 2.9 i
made up three configurations, for 1, 2 and 4M machines (see "tex.h").
similar sizing of the arrays can be done for TeX 3.0. The size in
memory of either the undumped or straight executable is no different.
Only the size on disk differs because the BSS section is now stored as
initialized data.

>
> A related question: has anyone ported BigTeX to the ST? I use the
> above undumped LaTeX and it blows up since I exhaust TeX's pool!!

dont need to port anything, just size up the arrays, and
re-compile. make sure that you size them so that you can still fit the
executable in memory.

Hi!

I have just killed my beloved ST :-(I tried to build a 2.5M ram expansion
(a new board for SIPs) and something apparently went wrong.
Now I'd like to get some info what I should examine inside that thing. I
only have a multimeter and a logic probe so please keep the instructions
simple!
Mainly I'd just like to know what's wrong and what it would cost to replace.
Is there any way to tell from a chip whether it's fried or not (pin 1=low;
it's fried etc.)? The symptoms are: it doesn't do anything, only the power
led is on. (Screen black, floppy dead...)

Any suggestions appreciated,
/hysky
hysky@polaris.utu.fi j.h.husgafvel

PS. I only have .5M installed (decided to test it first) It says on one
of the chips:aaa2801 J-07 nmbs 8837; is that a 256K SIP?

Jack,
you can do the following (written in turbo-c):

```
fonth[0]=vst_point(vdi_handle,INT_MAX,&dummy,&dummy,&dummy,&dummy);
i=fonth[0]-1;
sizes=0;
do
{
i=vst_point(vdi_handle,i,&dummy,&dummy,&dummy,&dummy);
fonth[++sizes]=i--;
} while (fonth[sizes]!=fonth[sizes-1]);
sizes--;
```

Afterwards you'll find in fonth[0..sizes] the available font-sizes
in reverse order (you'll have to swap the array). the idea
is that vst_point yields the next available font-size smaller-equal i.
But this does not work, when scalable fonts will be available.

2851. TT memory allocation

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-08 13:19:38 UTC
From: martin@minster.york.ac.uk
Message-ID: <678979177.28538@minster.york.ac.uk>
Source record: 47542
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

The Atari TT has two kinds of main memory, ST compatible ``ST RAM'', and faster, but incompatible ``TT RAM''. The developers' notes describe a new flag to an extended system malloc function to say which kind of memory should be used, and also says that there are two bits in the program header which say which sort of RAM the program should be loaded into, and which sort of memory should be returned by default, by the system malloc functions.

OK so far. My problem is that I can't find anywhere a description of *which bits* in the program header contain this information! If anyone could tell me which bits I should invert to get a program to load, and execute in TT RAM I would be very grateful.

Please mail any answers to me, and I will summarize to the net any solutions.

Many thanks,

Martin

>Daniel

Sigh. As everybody knows by now, GEMDOS does not check the mode you opened the file in when you try to write to it. You can read from a file you've opened for write-only, too. This is a bug, but it's the kind of bug we can't really fix. Perfectly reasonable programs and programmers have made this mistake, and their programs work because GEMDOS has never checked this. Fixing this bug means these working programs will break. I don't think the win is bigger than the lose. Naturally, nobody should rely on this bug on purpose.

In the case of networking, where you implement access rights more strictly than GEMDOS does inherently, I think checking the open mode before allowing a read or write is perfectly reasonable. I am surprised that KAOS to "fixes" this bug because it can make an otherwise-OK program "KAOS incompatible." I would be interested to know how many programs actually rely on this bug, and break under KAOS for that reason.

(Of course, KAOS isn't sanctioned by Atari in any way, and my understanding is that it might be illegal; it certainly is if it's a hacked version of TOS, as opposed to a complete rewrite without any Atari code or influence.)

Thank you for posting this, Steve. I would have done it, but I have been on vacation. I approve of (re-)posting small, freely-copyable, important Atari fixes to the net when there is a demand like this.

If you ever wonder if something is freely copyable, the best place to check is GEnie: if it was uploaded to the Atari Roundtable (*not* the Atari Developer's Roundtable) by somebody like Mike Fulton or ATARIDEV (J. Patton) or Bill Rehbock, you can reliably say that it's official and freely copyable. XCONTROL itself falls in this category now, and it's available on Atari Archive.

(The A.A. people asked me about another XCONTROL version, ostensibly from Atari France, and I had to say that it should not be made available: even if XCONTROL is freely available, and even if it was the genuine article and not an older rev or something, this other archive was probably just a collection of stuff and not "the official release archive." It makes a difference.)

2854. exception vectors on TT

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-08 20:00:46 UTC
From: vspicer@ccu.umanitoba.ca
Message-ID: <1991Jul8.200046.5734@ccu.umanitoba.ca>
Source record: 47541

Hello net world. Forgive if this question has been asked before, but is there a way to re-map the exception vectors on a TT-030 (in particular, exception vector 02, bus error)? What I'm doing is trying to debug a VME interface adaptor on the TT; so far trying to access VME RAM ($FE000000-$FEFEFFFF, A24/D16) comes up 2 bombs, which i'm interpreting to mean the VME device isn't responding to the address presented on the bus. I've put a logic analyser on the VME bus lines and monitored the AS* and Address lines, but NOTHING comes across when I try to access the VME ram locations.

So what I had in mind was to cycle thru all of VME address space waiting for signals on the AS* and VME address lines. Difficult to do when every execution gives you a bus error. Ideally I'd like to map the exception vector into a return, so it just keeps going. Or is that too simple minded?

The way I tried it was as follows:

The ST internals book describes that $008 contains a 4 byte address that is jumped to when an exception vector 02 occurs.

I just defined a little piece of code with an return (tried both RTE and RTS) and put its address in $008. The exception vector 02 no longer gives 2 bombs, but the machine locks up.

What am I doing wrong?

Thanks in advance
Vic Spicer

2855. init.o in Laser C

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-09 05:42:15 UTC
From: archbold@bluemoon.uucp
Message-ID: <51ys53w164w@bluemoon.uucp>
Source record: 47545

Hello ST wackos out there (including this one)!

I got a question about Laser C's init.o and MiNT. My brother (who is on vacation, away from our beloved ST <--poor sap) told me that he has problems with using programs written in Laser C inside of MiNT (especially when he tries to load multiple programs running simultaneously). From what he says, the program doesn't initiate itself properly and takes up too much memory (bad m_shrink perhaps?), so other programs can't load in.

He asked me to write a new init.o for him in assembler (the language I primarily work in), so I decided to see what's in the file. Using MonST I disassembled the object file and looked at it. Unfortunately MonST doesn't load the labels from object files into place like it does with the executables and GST files (when they have a symbol table).

Now, IF somebody has a disassembled init.o WITH the labels in place, then please e-mail the code to me. If not, then perhaps someone has structure of the *.O files symbol table.

And if my brother is intrinsicly wrong about the misbehaviour of Laser C compiled programs at startup, then please tell me, so that I can kill him for making an A*S of myself on internet!

Actually, if KAOS is what I think it is then it is perfectly legal. Here
is my understanding of what you get when you buy KAOS: a set of patches
and a program to apply those patches. This is legal, they are not distributing
TOS or anything that was derived from TOS, just patches to the TOS that the
buyer already owns. This type of thing has been going on for years, especially
when appleworks came out for the Apple IIe seris, people were patching
it to work on the older Apple II+s and Franklin ACE 1000s. In fact there
were companies that built 80 column cards for the Apple II series and
distributed programs to patch ... AAARRRGGGHHH ... that spreadsheet program
that came out a long time ago (one of the first, if not the first.)

Anyway that's my point. The buyer is allowed (unless I missed something
when I bought my ST) to make any changes to his/her computer as long as
they do not distribute it without permission from Atari/Apple/Commodore/etc.

Kurt Olsen
kurto@cc.usu.edu

PS - Allan, thanks for your input in this forum, it's always nice to
hear from somebody who knows.

From a legal point of view, I am allowed to do what I like with my Atari,
jump on it , burn it and change the code in the Roms.

All that KAOS does is to provide a bunch of patched that you can fix
your roms, after you copy the Roms to Ram and then apply patches , then
copy Ram to Eprom.

They are not selling Ataries code but there own.

What I do with my machine is my business.

Also if it is illegal why has Atari not shut them down, put up or shut
up I would say..

2858. Re: TT memory allocation

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-09 17:04:46 UTC
From: apratt@atari.UUCP
Message-ID: <2984@atari.UUCP>
Source record: 47551
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

martin@minster.york.ac.uk writes:
>OK so far. My problem is that I can't find anywhere a description of
>*which bits* in the program header contain this information! [about
>allowing program load and malloc to come from TT RAM]

I think it's there somewhere, but it's easier to answer this than find
it myself and tell you where to look.

One of the previously-unused longwords in the program header has been
assigned a meaning as of TOS 1.4. The least significant bit of this
longword is a flag which, when set, says "don't bother to clear the whole
TPA, just my declared BSS." The next-least significant bit declares that
the program may be loaded into alternative RAM (that is, non-ST RAM) and
the next bit declares that alternative RAM is eligible to satisfy Malloc
calls. The high byte of the longword has another meaning (too arcane to go
into here) and the other bits are reserved.

This longword is at offset $16 from the start of the program file. Thus,
the program header looks like this:

```
struct prg_header {
short magic; /* always $601a */
long tsize, dsize, bsize, ssize; /* segment sizes */
long unused; /* unused */
long prgflags; /* described above */
short absflag; /* if nonzero then no fixups */
}
```

I think program appeared recently in c.[sb].a.st which lets you set the
bits in prgflags.

```

This is utter bulsh*t rationalism. You are the very first person to flame
anyone who doesn't do things 100% by the book and you try to rationalize
that this bug is OK because fixing it would break programs that break
the rules? Come on. IMHO any programmer who opens a file Read-Only
and then writes to it deserves to have the program break.

2860. Atari ST executable format and fonts

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-09 22:43:09 UTC
From: crichmon@digi.lonestar.org
Message-ID: <1991Jul9.224309.27579@digi.lonestar.org>
Source record: 47549

I would like to know the format of a .PRG or .TOS file. Can someone give an explanation of how the information is arranged? How can I find the symbols and line numbers in a file that has all the debugging information in it? Any information or references to books/magazines will be appreciated.

Also, how can I load a font using a .TOS program? I do not want to use windows or dialog boxes...just change the character set of the ST. I vaguely remember some magazine article covering this, but . . . can anyone help here?

Thanks in advance.

Sigh II :-)
The list of "Why Bother Fixing" bugs is getting beyond a joke isn't it Allan?
These are just the ones I know about. Anyone know of any more?

* Lost 2 media clusters
* Malloc handles in OS pool
* Volume label identification
* Reset handling (why fix, just change the docs)
* Writing to files opened for reading
New:
* STE memory sizing

and although strictly not a bug:

* Why must we swap disks for every file when copying from one floppy
to another? Even on the TT!

>In the case of networking, where you implement access rights more strictly
>than GEMDOS does inherently, I think checking the open mode before allowing
>a read or write is perfectly reasonable. I am surprised that KAOS to
>"fixes" this bug because it can make an otherwise-OK program "KAOS

>rely on this bug, and break under KAOS for that reason.

Official Atari versions TOS *SHOULD* break the bad programs too. How are those
airhead developers ever going to learn? The Atari market is not big enough to
have any programs that are so important to keep bugs in TOS. Notice how many
developers wasted no time in updating their programs to work on the TT.

>(Of course, KAOS isn't sanctioned by Atari in any way, and my understanding
>is that it might be illegal; it certainly is if it's a hacked version of
>TOS, as opposed to a complete rewrite without any Atari code or influence.)

Illegal or not, KAOS fills a need. Atari, and you, seem totally disinterested
in supplying a fixed TOS 1.4. TOS 1.4 was released in April 1989.
One whole year later when loads of bugs had already been found we got it in
the UK. It would have been nice if we could have at least gained some benefit

from the delay. As soon as a bug is found it should be fixed. RAM versions of TOS should be distributed frequently and ROM versions updated at appropriate intervals. Such decisions are of course not yours to make but fixing bugs is.

Actually I think the KAOS upgrade works by reading your TOS into RAM, patching its bugs then writing a version to disk ready for programming on to EPROMs. So proprietary Atari code is not distributed.

BTW: Anyone seen an STE with TOS 1.62 in the UK yet? I thought not.
Does any STE owner really believe that Atari are going to let them have the new TT desktop?

Bottom line: While Atari are finally starting to produce 'upgradeable' machines like the Mega STE and TT they still see even TOS upgrades as a way of selling more machines. Sad.

I actually bought a copy of the Atari Mega ST4 Service manual from a Berlin firm at a substantial cost. The Best Electronics appear to sell them but the price entry is 'CALL'. I don't think I can xerox mine and sell it to somebody else. The sellers have to have a licence to do so (it is a copyright document).

Possible solutions:
(1) Provide a TSR for older GEMDOS's, so that people can check whether their
software is doing illegal things.
(2) Change things like that in future GEMDOS versions with a `backward
compatibility mode' set in a new flag in the program header.

Allright, but the point is that you don't have to be a registered developer
or such to get to them. They cost money though..

(Those good ol' days when you got a schematic with e.g. TV sets are long over)

I have been messing around with some Gem programming using Lattice Version 5
and I ran into some problems, most have been solved but I could not get the
objc_walk() function provided by lattice (i.e. not standard gem) to work. If
any one has used this functions and has got it working I would be most grateful
for example code on how to use it.

A good idea!! (...and blame all programmers who have done illegal things!)

> (2) Change things like that in future GEMDOS versions with a `backward
> compatibility mode' set in a new flag in the program header.

YAFPH? (= Yet Another Flag in the Program Header? ;-)
How many `backward compatibility mode' flags will the future GEMDOS version
have? (How about a TOS 1.0 and 1.2 ... compatibility flag?)

It's better to provide a TSR for these old programs (with the illegal
write on read-only files) to run on a "bug-free" future GEMDOS.

Yes. Another interesting fact: If you Fcreate() a file with the vol label
attribute, you're allowed you read/write the long the file is open. If it
is closed, the data are stored on the disk, but there's no way to get 'em
back. :-(

> This is a bug, but it's the kind of bug we
> can't really fix.

Technically no problem. Just another field in GEMDOS' handle structure
which is checked once before each read/write operation.

> Perfectly reasonable programs and programmers have made
> this mistake, and their programs work because GEMDOS has never checked
> this. Fixing this bug means these working programs will break. I don't
> think the win is bigger than the lose.

Most of the programs are correct. Our network file system really checks
the read/write permissions and we found only very few programs that break
down. The most common error in file handling you find are programs relying
on the range of handles they'll get back. For example, programs like
1st Word Plus, GFA-Basic etc. use signed char variables to store their
file handles. Other programs crash when they get DTA's in which the first
21 bytes do not comply to the way GEMDOS uses them. (We store other things
in the reserved area, normally nobody should care and we take care that
the old GEMDOS routines won't get any of our DTA's)

Another interesting bugs: Turbo C checks for handle numbers greater than
100. These handles are regarded as internal buffers and no real file accesses
are made, but TC tries to retrieve the file information from it's own
text buffer structures. So every network driver working with file handles
greater than 100 will cause a TC crash. :-(

I could tell a lot of similar stories. Even the TOS 1.0 file selector box
seems to be not quite correct in handling the DTAs. Just write a mail if
you want to know more... :-)

> In the case of networking, where you implement access rights more strictly
> than GEMDOS does inherently, I think checking the open mode before allowing
> a read or write is perfectly reasonable.

It's *necessary*... Our file server sets up a file system with divided owner/access group/default attribs (similar to *ix file systems). So we *have* to check the permissions.

But back to the old question (it's a theoretical one, but anyway...): Are you allowed to manipulate the date/time stamp if you just open a file for reading? Ok ... GEMDOS won't complain, but is it legal or not? Should a network file server accept such a request?

Daniel

Actually, I think you meant "a rationalization," not "rationalism." I would say that it is EXCELLENT rationalism: it is rational for you to to be conservative in what you demand of the machine and OS, and for me to be liberal in what the machine will allow.

>IMHO any programmer who opens a file Read-Only
>and then writes to it deserves to have the program break.

If it were your program, or a program you use and rely on, you might not feel that way. I am reluctant to fix this because I don't know what programs will break. It could be just a few little hacks, and it could be some big title which would cause a huge uproar. Who can tell?

2874. GEM and C help...

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-11 00:05:35 UTC
From: wernst@sdcc13.ucsd.edu
Message-ID: <21439@sdcc6.ucsd.edu>
Source record: 47562
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I'm a C newbie and am having a little trouble working with GEM. Is there a standard way of dealing with GEM objects? Beyond "objc_change," I mean -- I'll need to edit flags and such. I've fiddled with a few ways, none of which seem very elegant. Could someone post some code that will show how to load up a random number of trees and edit any particular attribute of any of those trees?

Thanks...

2875. FATSPEED problem

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-11 01:13:06 UTC
From: marc@sequoia.cray.com
Message-ID: <042129.6773@timbuk.cray.com>
Source record: 47563

Hi People,

Long time, no see... our news feed was slightly stuffed over the past week or so... Anyway, I tried to post something a while back, but I doubt that it got through, so I'll repeat it here. Apologies if it did manage to get to the net..

Well, having received lots of advice to install FATSPEED to overcome the slooow HD write problem I had, I finally got down to it. BTW, thanks to all those who replied -- one person even phoned!

My new problem is that I can't write to my HD!! It thinks the partition is full (rubbish!). Also, `show information' results in four bombs (illegal instruction exception). Renaming and deleting files still works :-|

I cleared out my AUTO folder, so I'm running only ICDBOOT.SYS, FATSPEED.PRG and STARTGEM.PRG (I run NeoDesk 2.06 over TOS 1.0). Still no joy. Does anyone know of a problem interworking with NeoDesk? I've had compatibility problems with it before, so I wouldn't be surprised... I haven't exhausted all avenues of research, but I thought, hell, someone out there must have done all this before me... :-)

As ever, any and all help much appreciated.

Cheers,

[M][a][r][c]

>
> * Why must we swap disks for every file when copying from one floppy
> to another? Even on the TT!

(This is getting a bit beyond 'tech' subject matter, but perhaps not
too far beyond)

I'm amazed that the new TOS versions haven't changed this. At least one
alternative desktop program fixed this years ago. It's been a long time
since I tried to copy files using a single floppy system without even a
ramdisk, but I remember the frustration when I started. I know there
are still new users who are undergoing similar frustrations.

> Illegal or not, KAOS fills a need. Atari, and you, seem totally disinterested
> in supplying a fixed TOS 1.4. TOS 1.4 was released in April 1989.
> One whole year later when loads of bugs had already been found we got it in
> the UK. It would have been nice if we could have at least gained some benefit
> from the delay.

Agreed. As Neil said in a previous posting, can we in the UK borrow
Alwin Stumpf for a little while please? Talking of TOS 1.4 fixes, is
there any technical reason to use the 'official TOS14FX2.PRG rather than
Karsten Ivanovic's TOS14FX5.PRG? Does the official fix use XBRA and/or
the cookie jar?

> BTW: Anyone seen an STE with TOS 1.62 in the UK yet? I thought not.
> Does any STE owner really believe that Atari are going to let them have the
> new TT desktop?

I haven't seen any 1.62s. There's no point looking for them in the
shops because, in Brighton at least, they all have ancient, dirty STFs
for the kids to try out games on. Still I do know someone who bought an
STE mail order recently. I'll check on it.

TT desktop? You've got XCONTROL, Neil - are you never satisfied??
:-) :-)

Cheers,

Graham

Well for one thing, I would sujest you get TOS 1.4, I now have it, and find
that is fixes a lot of Problems and head aches..

Note: Is Fatspeed the First thing in you Auto Folder, this is a Must..
If not get Autosort, this lets you put the Auto files in the correct order.

Things like that HAVE to be fixed if SOMEDAY an future TOS will allow
multitasking. So why not do it NOW and release a TSR bug fix for ill behaved
programs?

Let me just say that every program we have written thus far has either:

a) Been suggested to us by someone (they have a real need)
b) Been required by us (we have a real need). After all, necessity is the mother of invention.

On our STacy, the LCD screen is all but black (I sure wish Atari didn't sell us a unit known to have LCD problems, it's just about unusable) and finding the mouse on the screen (considering the screen dimness and blur) is nearly impossible. Thus, DC Homey allows us to quickly place the mouse in a known position.

Others have stated that they would find it useful when that pesky alert box appears in the middle of a screen and you have _no_ mouse cursor. I guarantee that I used to 'go to one corner' and work from that, but this is far simpler and quicker for hitting CANCEL (how accurate do you move diagonally?).

Anyway, keep looking for the weekly posts.

I _GUARANTEE_ that a bona fide use for every program we write does exist. Whether you find it of use is up to you.

- mike vederman

Unfortunately things are not so simple. This bug not only prevents
certain illegal programs from breaking, it can also cause one to lose
data (if I understand it correctly). Imagine a text editor that opens
a file "read-only", depending on GEMDOS to prevent the file from being
modified. What are you going to say to the user whose file gets
trashed?

I sympathise with the position you are in, but in the long run, I
think it is better to fix bugs (and provide TSR's for downward
compatibility where necessary) rather than leave them there for
developers to struggle with. You want people to write programs
"according to the rules", but this is a little much to expect if the
documentation doesn't match the reality. So you either need to fix
the bug or revise the documentation to make clear that it is the
application's responsibility to keep track of which open files are
writable and to never call Fwrite on a read-only file.

FATSPEED always has to be executed FIRST in the autofolder.

Either 1.) Use a utility that can change the order of execution

OR 2.) Take eveything out and replace the prgs in the order
to be executed.

I vote for fixing the bug. If it is not fixed, all those virtual
memory programming feats you are now probably busy with at Atari
to allow memory protection are worthless - I don't need to poke
into another's process address space to make it crash, it is sufficient
to open a file that this process currently is reading, and then to
overwrite it.

To ease persuading the marketing dept., all the major applications should be
tested using a TSR that controls file access, and those programmers
who ran into this bug should be notified.

Yep, that's what he meant all right. Hey, why not try it and see, or
ask for feedback from KAOS users 8-). A cold day in hell you'll ask
them you say??! 8-) 8-). Anyway, why not provide (or solicit) back
compatibility TSRs or such. I'd prefer a more and more reliable OS,
as a user, and would bug developers to make programs that worked with
it. The back compatibility TSRs would help me, and also developers,
since, they could simulate all earlier TOSes, depending on which TSRs
were loaded on a current (TOS wise) machine. Note: I mean TSRs
(autofolder loaded) not desk accs.

On another topic, has everyone else but me noticed the dearth of
commercial Software being advertised in the U.S.? Even places that
used to list all their software in what magazines are left, now
mention only hardware or games (notably Joppa). I need some stuff and
am scrambling to find it now. STs need help bad in the U.S.!!!

From: erik@mcrware.UUCP
Message-ID: <7307@mcrware.UUCP>
Source record: 47580

How can one latch on to a key press to execute some task. What I have in mind is running some resident code when some key combination is pressed.

As I see (just a guess though), you could write your own packet handler to grab those special codes (passing everthing else to the previous handler). In theory this sounds good, but would it work? In my Laser C manual, it says that your handler should take less than a millisecond. Is this requirement or recommendation (will longer routines crash the system or just slow it down).

Another approach I imagine would be to intercept some BIOS routine.

If you know how current programs (mostly TSRs I imagine) do this, I, as well as probably many others, would like to know.

For discussion, we can pretend our routine is either a program that takes a snapshot of the screen and saves it to a file (resulting in a long interrupt), or even more simple, a routine that blacks out the color registers, and restores them with another keypress (screen saver).

Erik R Johnson

2889. ICD Advantage Host adapter problems.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-11 23:43:49 UTC
From: rdt154k@monu6.cc.monash.edu.au
Message-ID: <1991Jul11.234349.9563@monu6.cc.monash.edu.au>
Source record: 47601

HELP!

I have recently bought an ICD Avantage Host Adapter and am having muchos problems getting it to work properly. My setup is as follows;

Mega ST4
External B drive, 720k
80Watt external power supply
Quantum Prodrive 40S, LUN 0
AdSCSI Host Adapter

all the relevant connections are correct, that I have gone through a dozen times. I boot from the floppy and all is ok. I run IDCFMT.PRG and it find the drive and recognises the type of drive. The formatting and partitioning goes on normally, no problems found. I prepare 3 partitions, C, D, E, 10Mb, 15Mb, 15Mb respectively. Interleave is set to 1. This proceedure run faultlesly.

Next I use HDUTIL.PRG. My set preference is to have the harddisk autoboot. Then I go to configure the driver, write verify is enabled, read and write caching is disabled and the remaining parameters are left at the default values. Then I exit the program and reboot the system. This is where my problems begin.

I allow 15secs for the hard drive to startup, then I turn my machine on. Two out of three tries the system will boot BUT no files will show in the C partition and GEM(TOS) will indicate an error with the drive. Yes I have run BOOTFIX.TOS (V2.10), it does no good. Randomly, C drive will not even boot.

What am I doing wrong, I have followed the instruction manual verbatim and also tried other approaches but no success. The DMA cable is the one supplied by ICD the SCSI cable I made myself (3 inches long). One other curious thing is that my Host Adapter is modified, ie, does not match the diagram at the back of the manual. U3 a GAL is replaced by a small PCB which has a GAL, 3 diodes and an LM311 comparator. What is this supposed to cure ???.

Any help would be most appreciated. If I am doing something obviously wrong then tell me, if not any ideas would be most welcomed.

Oh come on Allan! Who in their right mind is gonna create a stink when you break a program because you fixed a bug? If you change a documented practice you'd deserve some blasting (eg. resvector).

I say fix it now then issue a note to developers. If the companies that produced the errant software are still in business they'll release a new version for sure and supply it, or a patch, to existing owners.

TOS should not be allowed to suffer because of these programs.

2893. Re: crabs -- Screen-eating program for MiNT

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-12 08:49:24 UTC
From: ralph@laas.fr
Message-ID: <RALPH.91Jul12104924@orion.laas.fr>
Source record: 47391
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

There seems to be a problem with the crabexe.lzh file that was posted.
Neither Unix uudecode or uud or even uud on my ST could decode this
file.

In article <binaries.15.53@twitterpater.eng.sun.com> koreth@twitterpater.eng.sun.com
(Steven Grimm) writes:

```
| table
| !"#$%&'()*+,-./0123456789:;<=>?
| @ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_
| begin 644 crabexe.lzh
| M'\TM;&@Q+68< !:-0 0E6K%B "4-204)3+E144,*)]FFQF'NG[!@R#==Cz
| M0SK72P UW;UG[MOM>J6TW[!9;2FD7#2FHL$R,!K)<!$Y[P E97YY2AG?OFEZy
...
| M-44-MP8$40/Q)&)FC;N[@]\8+$">_"0G,S-.MNAR!;:^RC0$5AC:LUC.(LF/w
| M<\=+6)+<S:26 N/R[BH+F5;9=W#R>.@[0?,ISZ;SD$2P6N+8TPQ^;:!;@W!v

| ..8>OG83<SX LGU[._T "Jt
| s
| end
```

On the ST uud complained about the sequence letter <J> in the next to
last line. The Unix versions all did a nice `segmentation violation.'
Have others successfully recovered this file?

Cheers,

I would agree with Atari's position on this matter is a large part of the
installed software base made use of (illegally) this bug. Has Atari done any
research in this area? Are there many commercial programs that write to
read-only files? Other companies have kept around certain side-effects from
routines in their OS because developers made use of them, and they too were
bugs.

This seems like a very dangerous type of bug to choose to leave in any OS.

OK, now that everybody has decided they would like this fixed, why doesn't somebody (DC, hint, hint) write a auto program that fixes this. Then after it is distributed, and everyone who thinks the write-to-read-only files is a problem can see what kind of effect it will have on the current software.

Personally I think that this would give us (us being everyone, including Atari) a better idea of what the effects of repairing this would be.

Anyone else think this is a good idea?

Here Here...

This bug (which I din't know existed till recently :-) should go, if it breaks programs tough... patches will appear or the program will die. This bug should be elliminated and at the same time the braindead fixed pool malloc should go too. I really don't care if this breaks programs that think successive mallocs will be contiguous. I can think of many cases in which they may not (since Malloc is first fit).

While you're at it can we have about 3 dozen more windows please
(Same brain-dead thinking --- yes I heard the excuse about n+1 but its just that, an excuse !)????

I just looked up the Fopen call, and it seems to me that it's
a pretty trivial patch on any application found opening a file in the
wrong mode. If there are applications around which have this bug, but are
unsupported at this time, it wouldn't take much to patch them. It certainly
doesn't seem to be as sticky as the applications which expected malloced
memory to be contiguous.
Sometimes a blanket policy is not the best.
Add me to the list of people who'd love to see more windows, even
without multitasking.

Good idea so far. But I think we should swap lists of software tested and
the results. Ok, this would mean creating black lists of software with this
kind of bug. And I think (or better, I hope) that the software companies
do not wish to appear on those lists.
I would also vote for publishing these lists within other nets or the
atari magazines. RFC

2903. Help with UniTerm

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-13 15:26:14 UTC
From: 72347.2767@CompuServe.COM
Message-ID: <910713152614_72347.2767_EHA52-2@CompuServe.COM>
Source record: 47590

I've been using UniTerm to connect to various Vaxen since 1986. I've had one nagging problem since I first began using the program. Quite often when I use UniTerm with Eve or EDT pressing the Return key causes a Bus Error. The fault looks as though the program references a string as if it were the address of the string. The error has been present in versions 2.0b-2.0e (the highest version I have). It's been present on my ST with TOS 1.0-1.4. (I have a color system.) And the VMS versions range from 4-the latest for 8650s (forget the revision number).

I'd be interested to know whether anyone else has experienced it and whether there is a known reason for the failure. It causes some real problems because UniTerm takes over a number of system vectors and doesn't reassign them on error exits (ever heard of safe signal processing?).

Please respond directly as I don't often get to read the news group. I never get to read comp.sys.atari.st in fact.

Message-ID: <9107132058.AA26372@ucbvax.berkeley.edu>
Source record: 47592

I've heard that SOME TTs had problems with the Spectre GCR cartridge, but I never tought my brand new nice TT would be one of them. Does anyone have any incling abut what is causing this?

The symptoms are...

The machine locks up as soon as any attempt at accessing the floppy drives with GCR encoding. This happens both in Spectre itself AND the GCRTEST program supplied with Spectre.

I'm trying to run Spectre GCR Version 3.0 (which is supposed to be TT compatable) on a brand new (as in I recieved it today) TT030/8.

Steve

PS. Isn't it a bit of a pain how the keyboard cable gets in the way of cartridges!

>is running some resident code when some key combination is pressed.

If you really want to link it into the ikbd interrupt routine, the good news
is you can do it without a packet handler. In the vast majority of cases though
it is more applicable to install your own bconin handler by linking into the
bios vector. There might even be a use for intercepting gemdos (tos) calls
but I don't see it right now.

The choice of intercept method depends on what you are intending to do.
If it is unavoidable to install the handler in the ikbd vector and your
routine is lengthy, you could set a flag which you actually process somewhere
else.

Oh, and if you wanted to be really silly you could install a routine in the
keyboard processor itself which sends your own user-defined packets. This
might have some serious application if it is installed as a ROM replacement
for the keyboard processor, but that requires extra hardware.

2907. floppyBIOS FAT handling.

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-14 04:16:02 UTC
From: adamd@rhi.hi.is
Message-ID: <3379@krafla.rhi.hi.is>
Source record: 47594

Just bumped into this one. The TOS bios routines cannot handle larger FATs
than 5 sectors. This puts an upper limit of 1704 data clusters on a floppy
disk. Therefore in order to get more than 1704k of data (including directories)
onto an HD floppy, it is necessary to use 4 sectors per cluster and 3 sectors
per FAT to maximise space.

With this limit, 8 sectors per cluster will be necessary for ED disks.

DD disks with 2 sectors per cluster never need any more than 3 sectors per FAT,
and even if the FAT had 16-bit entries that would only use 4 sectors.
Why is the default size set to 5 sectors per FAT ?
Has this been fixed in more recent TOS versions?

tolk@opal.cs.tu-berlin.de (Robert Tolksdorf) writes:

|... the idea
|is that vst_point yields the next available font-size smaller-equal i.
|But this does not work, when scalable fonts will be available.

Checking font sizes still works with FSMGDOS, and it is still important.
The effects buffer used for algorithmic text effects (such as outline,
bolding, etc.) is based on the largest font size in the FSMGDOS configuration
file (EXTEND.SYS). A program should not use algorithmic special effects
for point sizes larger than the largest returned by vst_point().

The important thing is that it's not necessary to check *all* point sizes
available under FSMGDOS, for obvious reasons. But it still works, for
compatibility with non-FSM-aware programs, and it's still important to
find out the largest point size you can get from vst_point().

I doubt this is real. My hard disk surely has a larger FAT...

> With this limit, 8 sectors per cluster will be necessary for ED disks.

TOS doesn't support this in all versions. BTW: How do you connect an ED
drive to the ST :-?

Probably this "limit" only exists when using 12 bit FATs? Perhaps one should
try using 16 bit FATs on floppy disks also, if you write your own formatter,
this should work.

> Why is the default size set to 5 sectors per FAT ?

The old problem: Messy-DOS compatibility. DOS isn't that flexible as TOS...

Daniel

2911. Danger of Plugging Foriegn Peripherals in Joystick Port

In article <2987@atari.UUCP> kbad@atari.UUCP (Ken Badertscher) writes:
>It isn't Atari's fault
>that some people like to program over the edge.

It IS Atari's fault that developers and other programmers, after 6 years, still do not have adequate documentation of where the edge is. For example, I do not know where in my developer's documentation it is stated what can and cannot be assumed about sp and a0 in desk accessories. I'm not saying that it isn't there; only that I don't know where to find it (and out of curiousity I just spent several minutes looking for it). This forces programmers to figure out the rules for themselves based on empirical evidence and superstition; it's no wonder that they often get it wrong!

Your and other Atari people's participation on the net is very helpful for filling in the gaps in the available documentation and is much appreciated! But more and better documentation, even at this late date, would still be very helpful.

TOS version 1.2, I've been putting off upgrading until I can get a bug-fixed
version 1.42 or higher. Atari UK said 1.42 doesn't exist, so I wait.

I have only observed this twice, before deciding to play safe and use 2048-byte
clusters. The first time was with 5 sectors per FAT, the disk accepted 1704k
of data without complaint and shortly afterwards I got the GEM error message
"Disk does not have room for this operation". I had 54k left on the disk and it
would not accept a 42k file. Further investigation revealed that the FATs were
full, *AND* that the bottom of the second FAT had been overwritten either by
garbage or FAT_1 information. There was no flowing over of the second FAT.

The second time was after I tweaked the BPB in the boot sector to 6 sectors
per FAT. This time the copy operation failed in the same place with the same
error and the 6th sector of both FATs was empty. Each time this occurred was
immediately after reformatting the disk to 1764k (raw space) and attempting
to fill the disk with data. The only way I could get the stuff on the disk
without compressing it was by increasing the cluster size so that enough FAT
space was available.

>IMHO, with MultiTOS more windows are not just a convenience, but a necessity.

It takes a while for our suggestions to sink in but I think it's worth it.
I've seen a lot of our much earlier gripes turn up in the later TOS versions.
eg.
TOS 1.4: Auto run GEM prgs, Rename folders, Reset from keyboard.
TOS 1.6: Mouse usage in file show
TOS 2.x: Read only files marked in window, More windows (7?)
Key binds for desktop functions, programable function keys ...
(Actually this is a long list)

So let's start the pressure:-

FIX THE BUGS! ADD MORE FEATURES! RELEASE IT!!

2918. OVERSCAN

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-15 08:48:59 UTC
From: David_Galloway@mindlink.bc.ca
Message-ID: <6674@mindlink.bc.ca>
Source record: 47635

Well, I need some help as well.

A friend, Jeff Koftinoff installed the widely distributed OVERSCAN mod on his MEGA 2 and I liked it so much I decided to install it on my aging(very old) 520. (board C070115 REV. 2B)
Serial # A1 1016540 8 1985)<-year! Well... I put together the small circuit outlined in the documents, and it seems to switch the DE signal on and off properly, however the Screen is not synchronized. I suspect that the HSYNC and VSYNC signals need to be conditioned (perhaps buffered?) Anyway, although I understand the basic workings of the circuit and the logic, it doesn't work. I built two and they both do the same thing.

I also had to upgrade my roms to 1.4 and thankfully that worked fine.

I would appreciate any advice from people who have done this modification. As a carrot for Karsten Isakovic and/or Stefan Hartmann I plan on supporting the OVERSCAN at work if I can get enough test machines running flawlessly. (yes I eventually would like to get a couple of the AutoSwitch OverScans)

Thanks for any help any one.

>compatibility with non-FSM-aware programs, and it's still important to
>find out the largest point size you can get from vst_point().

Well, I think my last statement was not that precise. My code-fragment
works, when scalable fonts are available. What I meant was that the
results not always do make sense. A list of avalable fonts from, say, 5
to 50 points, including every point-size in that range, would not be
very wise - just take wordprocessing, where a font of 15 points is
simply forbidden from the aesthetical viewpoint. We had a discussion
about this topic on the german `MAUS'-net and thought, it would make
sense to offer a fixed range of point-sizes - say, 8, 9, 10, 12, 14, 20
- , if scalable-fonts are available, instead of the mentioned method
with vst_points. But we ended up with a lot of developers, saying that
it will be possible to detect fsm-gdos or scalable fonts, but no-one
told us how, since Atari won't let this information out. Therefore, my
code-fragment should be extended, when these informations are
available.

ciao Robert

I am considering upgrading to an Atari TT. As I understand it TT's
only come in two models: the TT/2 and the TT/8. Is the ST RAM *only*
on the mother board, or is half of it on the extra TT RAM card?

Also what kind of RAM is in the two types of RAM for the TT: SIMMs,
SIPs, chips, or some mixture of the above? I would prefer getting a
TT/2 and upgrading the ST RAM to 4 Mb in the case that SIMMs are
involved. I would probably later on, sometime next year when the
European plant for 16 Mb chips starts operation, get the faster TT RAM
when prices would fall.

I've just installed Wizztronic's compatibility plus board in my Mega 4, and
now have both TOS 1.0 and 1.4 available at the flick of a switch.
Installation was straight forward (only 1 wire to solder), but now I have
the following problem:

TOS 1.0 can only handle hard disk partitions up to 16MB, but since
I've been running 1.4 for some time now, I've got a number of 20+ MB
partitions. 1.0 seems to be able to READ data from these partitions
ok, so long as it resides below 16MB. Anything above the 16MB level
on the partition appears scrambled. I don't dare WRITE to such a
partition under 1.0. I'm thinking about repartitioning my drive using the 'new'
BGM scheme (larger cluster sizes), but otherwise keeping my partition
sizes the same.

Does TOS 1.0 support BGM partitions?
Will this let me get past the 16MB limit?
What problems might occur by using larger clusters?

(I've got an ICD Advantage host adapter with version 4.x.x software,
though I just downloaded the 'latest' v5.x.x)

neil@cs.hw.ac.uk (Neil Forsyth) writes:
>Oh come on Allan! Who in their right mind is gonna create a stink when you
>break a program because you fixed a bug? If you change a documented practice
>you'd deserve some blasting (eg. resvector).

I guess you weren't around on GEnie when I suggested that I fix a bug in the BIOS trap dispatcher HUGE stink because it would break those programs that relied on getting a pointer to an internal table in a certain register. Apparently this is a favorite trick of the cute-little-hack crowd, and they were all up in arms that I would take this away. It's not documented, and it *is* documented that I am *not* required to return anything useful or consistent in garbage registers d1-d2/a0-a2.

So people, right mind or no, DO raise hell when seemingly-innocuous changes are made or suggested. My logic is not as off-the-wall as you seem to think: it's based on experience.

Another subject in this thread relates to keeping track of Malloc'ed blocks using a fixed-sized pool of memory descriptors. Again, changing this creates all kinds of hassle -- much more than disallowing writes to read-only handles. Having successive Malloc's no longer contiguous is only part of the problem. The other, bigger part is that many programs access memory outside what they own -- a few bytes before or after, or memory they've just released with Mshrink. Currently, those places are relatively safe: if you just used Mshrink to release memory, then it's not used by anyone. If you run off the top of a block you've Malloc'ed, it's likely that either the next few bytes are free, or they're owned by you (via a different Malloc). So at in the likely case things will work, or you will mess up your own data and bomb. But you won't corrupt the whole memory architecture of the system. If you write over the OS's memory descriptors, though, you get in BIG trouble. Without validation, the result is really wierd behavior. With validation, the result is a panic ("Memory data structure corrupted").

Memory protection is a subject of current study for the TT, but not all the world's a TT (yet).

2926. Help! I think I fried something!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-15 18:38:17 UTC
From: petcher@wuphys.wustl.edu
Message-ID: <1991Jul15.183817.16654@wuphys.wustl.edu>
Source record: 47615

In trying to add some shielding for the internal floppy in my Mega ST (for the Spectre GCR disk read problem), I apparently did some damage. When I first put the machine together and booted, "there were bombs".

So I put everything back to its original state, and booted, and there were still bombs. The behaviour differs depending on the disk in the drive. However, the strange thing is that when I boot from a floppy (a disk with a boot sector program jumping to the old TOS.IMG on disk; remember that from back in 1985-6 before TOS was in ROM?) everything works! But of course, running some old disk based version of TOS 1.0. :-(

What could be wrong? Since everything seems to work fine when booting from floppy, I guess it boils down to what is needed for a ROM boot that is not for a floppy boot?

Understandably, I had thought I might have fried my ROMs. But in retrospect, doesn't the machine first go to the ROMs and then jump to the floppy to find out if it is bootable. If so, that would indicate that part of the ROM is working properly.

However, when I fired up the debugger and looked at address $FA0000 (the beginning of the ROMs), I saw only garbage. (not random garbage - but ordered garbage) This is true throughout the first chip. When I look at the address $FC0000 (the beginning of the second chip - I have the two chip set), I find what looks to be sensible code. I am not sure what constraints the operating system puts on this, as the old system only had 64Kb ROMs, but I would expect that if all were healthy I could read the ROMs that are actually in the machine. Maybe someone can try booting from disk on a healthy machine and take a look at the ROM addresses to see what happens.

Any ideas on how I can track the problem down? I called a local dealer, and he said I could bring it in and he would get around to it in about a week and a half, but he DOESN'T accept appointments. Only on a first come, first serve basis. :-{ As far as I know, there is no one else with a diagnostic kit in the (St. Louis) area.

This is of special interest, so responses should probably be sent directly to me.

Thanks,

Don Petcher petcher@wuphys.wustl.edu
petcher@wuphys.uucp

A small anecdote about this:

One upon a time I wrote a simple and silly utility (a filter) that
opened two files, one for input and one for the result. Due to a
small typo the output was written into the input file which ended
up quite - er - strange. As I wrote this small hack in Basic, I
blamed GfA for this one, and did not think further about it. Now
I know better :-)

I don't know much about ED-floppies except that a friend of mine has
one in his NeXT... As far as I heard they can be connected via SCSI.

Is this correct ?
Is there some other interface (which one) ?
Would putting one onto my SCSI-bus (ICD +) give any problem except
formatting perhaps ? It should be usable similar to a SQ555-drive,
shouldn't it ? (I could even use it under Minix then, I guess...)

What are the prizes on drive and media ?

If you haven't guessed so far: I really hate disk-swapping for a hd-
backup, and life is tough with a 195MB-drive...

Oh yea?
Well you and I today have ALOT better support as developers then ANY other computer...
You can get it relatively cheaply IF you are writting software..
If you get onto Genie and spend a little time (I spend $20 a month and get ALL the messages and a file here and there..)
If you have a problem it normally is helped out within 24-48 hours...
Try that with apple..
With apple its ALOT harder...
You have to spend $700+ for a license.. Have to submit all sorts of paperwork and end up spending ALOT of money on tools just to make anything work.. Course if you have money to throw away and you don't mind being shoved around by apple thats ok...
(Of course you COULD pirate it all....)
With the IBM's you have basicly books that are written but have no real support otherwise...
Amiga is about as good with support as atari though...
ANY atari developer NOT on GEnie is screwing themselves over..
REALLY!
Now that I dumped my girlfriend and have a new one 150 miles away I can get back to some serious programming.. ;-)
Although now I am also cycling like 100+ a week too.. To much to do and too little time....

As long as your not shorting the +5 to ground or adding power of your own it shouldn't hurt it..
(Shorting the +5 to ground should only turn off your computer.. ;-) Unless of course you leave it connected for too long.. Do that and you could have the chance to find out how much smoke certain parts hold.. ;-))
Hmm, who was it that said it was the smoke inside electronic parts that make em work? ANd that if you let the smoke out they didn't work right anymore?

I would suggest trying cables you KNOW work...
Also call ICD.. They are normally very helpful in that area..
The fact that the drive formatted doesnt really mean much..
It already is formatted when it arrives..
However setting up partitions and installing the ICDBOOT.SYS should make it
all available..
90% of all hard drive problems are cable problems...
Try different cables.. If that dont work then call ICD...
Those changes were made to help the new host adapters work better with
Ste's and with megas with internal hard drives..
(Thats what I have heard anyhow..)
Also make sure your drive is terminated...
Good luck!

2937. 68000 rec. adaptor and 68010/STe

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-16 04:22:28 UTC
From: AAron@sun.soe.clarkson.edu
Message-ID: <9107160422.AA13044@sun.soe.clarkson.edu>
Source record: 47613

After reading about Howard Chu's need for an adaptor to use 680x0 in his STe, I remembered the 68010 I found, and the reason I never used it... The adaptor...

I made a little square of plastic the size of my 68000, and bent solid core wires around the sides to simulate 68 pins. Then routed each wire to the appropriate pin on the 64pin rectangle socket. 128 solder points, yuck!

The square package 68000 has pin 1 in the middle of one side, and is marked by a dot. The pins then count counterclockwise all the way around.

Extra pins on the square package are 17,18,31,57. Ignoring these, the signals are consecutively in the same order as the rectangular package. (Strange how the last four weren't the extras)

After inserting the 68010, and pushing the plastic piece into my CPU socket, I couldn't put my STe completely back together, but it booted correctly, and GEMINI reported upon 'cookie' that I did indeed have a working 68010.

I thought things were quicker, but after running Quick Index 1.5, I saw that I must have been wrong. (BTW, cars really do drive better with a full tank of gas :)

Quick Index 1.5 reported:	68010	68000
CPU memory	99	100
CPU register	100	100
CPU int divide	116	100
CPU shifts	100	100
GEMDOS I/O	100	100

The BIOS and GEM were also reported just a bit slower in 68010 mode, and I think that is probably due to the CPU memory difference.

Well, since I don't weigh divide speed over CPU memory speed, I have restored my original 68000 :(

Besides allowing more for 68010 SPECIFIC programs, is there any other advantage to having one installed? Anything QIndex might not have mentioned?

Well, I kept at it and I fixed my problem (I was using a transistor that was below spec). So my paranoid fears were, once again, unfounded. Well, now, even as I type I have a glorious 688 by 480 mono screen. It sure is cool! Thanks!

I am impressed by the fact that most software I have tried either works, or needs minor fixes (mostly in scrolling routines it would seem.) With this large screen and TOS 1.4 my circa 1985 520 ST seems almost reborn! :) Now I suppose I should upgrade the memory. Any suggestions about that ? (Please Email me if you have an inexpensive way to go 4megs; prefer SIMS)

2939. AT Speed C16 / AT keyboard (followup to my own posting)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-16 10:43:28 UTC
From: jensting@diku.dk
Message-ID: <1991Jul16.104328.13120@odin.diku.dk>
Source record: 47621

Hi

Some time ago I posed the (unwilllingly) rethoric question

>Having installed the c't external keyboard (AT keyboard into MIDI
>port), and being interested in buying an AT emulator (for programming,
>not for use ;-), I need to know if the available AT emulators
>(ATSpeed(+), ATOnce, PC-speed with 286 extension(?)) will accept the
>external keyboard.

Now I know..

I bought an AT Speed C16 (16 MHz, 80287 socket, all CMOS) and
installed it. The first impression of the software is that MIDI data
seems to hang the system. My guess is that the AT emulator does its
own interrupt handlng, and hence doesn't take too kindly to the MIDI
data from the keyboard hack (which involves using the MIDI port for
input). So, the short answer to my question above is that the keyboard
extension doesn't work with the AT emulator (at least not with AT
Speed C16).

Apart from not being able to use my PC keyboard (which is perhaps a
rather unrealistic wish anyway), my main gripe is with the DOS
software, i.e. DR DOS 5. DR-DOS 5 which is included (at least in the
UK), doesn't like my harddisk AT ALL. Starting with a freshly
repartitioned Quantum hardisk (on an ICD adapter) and proceeding as
per instructions, the AT emulator was unable to write anything
sensible to the harddisk, getting sector seek errors! Proceeding not
according to instructions (skipping a DR_FIX program), the emulator
could copy files to the harddisk, but the files were not visible
running the ST !

A successfull installation was made using PC-DOS 4.01, using the
following procedure:
-1 redo partitioning to clear the partition (probably
unnecassary)
-2 Start the AT emulator, insert INSTALL/SELECT floppy from
DOS 4.01, quit INSTALL/SELECT, format bootable partition
(just to be on the safe side), using `FORMAT c: /s/v'
-3 use FDISK to make the partition (aka drive C: on the AT)
``active'' (bootable ??). It's now possible to boot DOS
from the harddisk.
-4 with an ST editor create the file CONFIG.SYS in the AT boot
drive, with the contents ``DRIVEPARM=/d:0/f:2/t:80''.
-5 CD to PC-DOS INSTALL floppy, type AUTOEXEC and let the
install/select program do the rest.

Essentially, after step 3 you have an AT that boots of the harddisk (if you remember to tell ATSpeed to do so..). Step 4 tells DOS that it's OK to format with the command FORMAT A: /F:720 ...

The partition above is the partition that you chose to make the DOS boot partition (DOS drive C:). Mine is on ST partition F:. So, the step before all these is to assign ST partition F (or whatever) to AT partition C, using AT_INSTALL.PRG

It might be possible to make ST drive C the same as AT drive C, but I haven't done so.

Using Norton SI, I got the following performance indexes:
Computing 8.1
Disk 5.3
Index 7.1

I'm disappointed with the disk index, because I know that the drive (Quantum Impulse 105) does approx 1 MB/s, av. seek 20 ms, using ICD speed test, and ought to be faster than that.

In an optimistic fit, I used Norton Speed Disk to optimise an ST partition (which had not been modified at all during the AT installation), and got 5 bad sectors. Using ICD Cleanupdemo, I got no bad sectors (and no errors), but Speed Disk required me to run Norton Disk Doctor to map in the sectors as bad. Strange. After completing Speed Disk, ICD cleanup gave no error messages, and I sure hope that the files on that partition are OK (I did back it up before, of course..).

Well, further news as events warrant.

Well. Then release a TSR that hooks into Malloc(), which enlarges the
allocated block and which puts some magic numbers at the start and the
end of the allocated block. Further calls to Malloc() could then check
the integrity of this information and inform the programmer that he has
wrtitten data beyond th end of the allocated block.

It won't work unless you have a special floppy driver. The BIOS floppy driver
always assumes 12 bit FATs.

>
> While you're at it can we have about 3 dozen more windows please

Agreed. Big screens need more windows, as well as multitasking. It can't be that difficult to implement. NeoDesk has no trouble in offering us seven windows.

And I agree, too, that it's a better idea to fix bugs than not to fix them on the grounds that some programs might break. If Allan knows of a number of 'big' programs that rely on the read only/write bug, then maybe the developers should be told about it. (They wouldn't do things that way deliberately, would they? Or am I being naive?)

The way to do it would be to announce which fixes and enhancements were contemplated, and let developers comment on them. There may well be a few things Atari doesn't want the competition to know about and would therefore want to keep secret, but neither fixing this bug nor adding to the number of open windows would, IMHO, fall into that category.

A bug fix *and* a round tuit would be a terrific incentive for Ken Badertscher to fix MACCEL3, eh Ken?

Wot, you got something against $AA006E? Well, it is a REALLY silly cookie value (and in fact, intentionally non-printing). It works much better hex-dumped, you see, if you squint at your monitor like I do, the AA sort of looks like an M, and the 6E sort of looks like "SE", which gives you the word "MOOSE" in a hex dump. Truthfully, MACCEL3 is a MOOSE accelerator!

'macc'? Naah, I should use 'Maus' :) And I should have used 'Maus' for the CPX, too!

Fix this problem fast. You can't afford a bug like that if you are MultiTasking (Whatever form you use). On my Amiga I download messages i ZIP format, UNZIP them, Filter the text, REZIP and Transfer the file to disk. I download about 30 message bases in 2-3 hours. If I presently try to UNZIP a message file while downloading, or try REZIPPING the file while it is being filtered the O.S. will give me a error message and prevent me from making such a mistake. If I had that sort of bug in the O.S. PKAZIP would surely corrupt a message base or two. I know this is true because I make the mistake atleast once a week.

FIX THIS BUG OR DON'T MULTITASK USING DA, MULTIGEM, OR WHATEVER.

2946. Sozobon Stack Size

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-16 18:06:53 UTC
From: brad@bcars241.bnr.ca
Message-ID: <1991Jul16.180653.6203@bigsur.uucp>
Source record: 47626

Basically as an exercise in the power of the Sozobon C Compiler before trying to put together my own stuff on it, I pieced and twiddled with the Zoo 2.1 sources till I could get Sozobon to compile them. Good enough. Now I have a zoo.ttp, but it seems to be grumpy at the size of stack Sozobon defaults to (4K).

Now, I updated unsigned long _STKSIZ to 16K, and found that it got rid of my stack overflow error, and now just bombs. So, my first guess is that the stack space is not being reserved according to _STKSIZ at link time, and that some code needs to be tweeked or just re-compiled with the new _STKSIZ defined. Somewhere in sozoinit.o I find stack memory being allocated to 6K. Aha. I cc this with the new _STKSIZ in mind and move the sozoinit.o file in place of the old one in \lib. Still no good.

That takes me to midnight, and I have work in the morning, so I think of two things:

1) Some library (dlibs.a?) needs some parts rebuilt with the new stack size. Or maybe there is something in dstart.s that needs to be tweeked. Lots of guesses in this general direction etc.

2) Chances are someone has had to re-size the stack in Sozobon or Sozobon is close enough to Alcyon in this respect that a comparison can be drawn, and so someone might save me reading a lot of source code.

At this point I go to bed. So I can compile Zoo 2.1 but besides getting the help option to work, it doesn't do much. So any Sozopros out there? Please post, as mail to this address gets cut off at the knees.

brad

Source record: 47630

I had the same kinds of problems with my Mega 4. I think the DMA cable is too long, or some other such nonsense. Sometimes I could boot up and see all the directories on the disk, but trying to execute any program would always fail due to read errors. I use the ICD stuff on my STe now and only have occasional boot problems (4 bombs after hitting the reset button. A keyboard warm-boot usually works OK). I'm looking for a BMS 200 to use in the Mega now, tho I may just go back to Supra. At least their stuff always booted and never gave me read errors...

Hm... BIOS and GEM might be slower because the 68010 shoves more words onto
the stack for exceptions (traps & interrupts & such). Don't know why the
CPU-memory speed would be slower, must be an artifact of the QIndex code.

Don't downplay the importance of integer division - multiplication is probably
(just a guess, I haven't checked) also speeded up, and both of these operations
occur pretty often in graphics routines and a lot of other places as well.
Of course, I dunno if 16% is enough of a speedup to be noticeable. (Consider -
I doubt that TOS uses table lookup for pixel drawing, so when you say draw
a pixel at row Y column X, the code has to retrieve the width of a line,
multiply by Y, then add X and the screen base address to find the byte to
change. Line-drawing routines probably only do this calculation once per
(vertical or horizontal) line, but otherwise you're talking a very heavily
used instruction... That 16% may be enough to noticeably improve the
responsiveness of the GEM stuff.)

I guess the only other advantages would rely on having 68010-specific code.
Loops taking advantage of 68010 loop mode would probably run twice as fast,
depending on the operation. There aren't a lot of new instructions, just
enough to support virtual memory. Lessee... BKPT, MOVE from CCR, MOVEC,
MOVES, and RTD. BreaKPoinT seems to be for the convenience of external
debuggers. MOVE from CCR is necessary because MOVE from SR is privileged
on the other processors but not on the 68000. MOVEC and MOVES are enough
to let you double or quadruple your usable address space by directly
controlling the Function Code outputs. RTD lets deallocate parameters
automatically on return from subroutines. Too bad it'd take some effort
to make it useful...

Whoops, I made a serious wording error. What I meant, of course, was the
floppy driver bios. Obviously the hard disk is handled by a separate driver.

[...ED disks]
> TOS doesn't support this in all versions. BTW: How do you connect an ED
> drive to the ST :-?

This is usually done by SCSI and therefore gets new driver code. However there
are two possible ways to connect it to the FDC:

1) via normal HD floppy interfacing methods (16 MHz clock to WD1772) and by
letting the drive rotate at 150 rpm. This has the same data transfer speed
as HD floppies.

2) by replacing the WD1772 with a more capable chip. Suggestions anyone?
I envisage something with a built-in divider so that it is possible to select
between 4 different data rates (125kb FM; and 250kb, 500kb, 1000kb MFM) simply
by setting the relevant control signals. I don't mind if it's a 32-pin package
but 40-pin would be unnecessarily large.

> Probably this "limit" only exists when using 12 bit FATs? Perhaps one should
> try using 16 bit FATs on floppy disks also, if you write your own formatter,
> this should work.

Is there any way of using 16-bit FATs on a floppy without writing a new
floppy driver? There is certainly no documented field to specify FAT entry
size on the boot sector. Yes, there is a way of telling by looking at the
beginning of the FAT itself but it is not foolproof and TOS ignores the
```

first two FAT entries anyway.

> stack overflow error, and now just bombs.

What exactly did you do to ``update'' the value of _STKSIZ? If you
did this:

```
extern long _STKSIZ;

/* some stuff, then */

_STKSIZ = some_big_value;
```

... it won't work, because _STKSIZ has to be set BEFORE your program
starts executing.

> So, my first guess is that the
> stack space is not being reserved according to _STKSIZ at link time, and that
> some code needs to be tweeked or just re-compiled with the new _STKSIZ
> defined. Somewhere in sozoinit.o I find stack memory being allocated to
> 6K. Aha. I cc this with the new _STKSIZ in mind and move the sozoinit.o file
> in place of the old one in \lib. Still no good.

Ah.... I don't know what sozoinit.o is doing. It's not part of dlibs,
and it's not part of the Sozobon C distribution. Use it at your own
risk. It may use _STKSIZ in a different way than dstart.o, which is
the ``proper'' startup module for dlibs.

If you're using Sozobon cc.ttp, it will link dstart.o automatically.

> That takes me to midnight, and I have work in the morning, so I think of
> two things:
>
> 1) Some library (dlibs.a?) needs some parts rebuilt with the new stack size.
> Or maybe there is something in dstart.s that needs to be tweeked. Lots
> of guesses in this general direction etc.

Here's what happens.

IN dstart.o, the startup code checks the value of _STKSIZ, and uses
it if it makes sense:

```
move.l #__STKSIZ,a2 * a2 = &_STKSIZ
move.l a2,d2 * if __STKSIZ is undefined
beq minimum * use MINSTK
move.l (a2),d2 * if __STKSIZ is positive
bpl setstk * use __STKSIZ
add.l d3,d2 * if __STKSIZ is negative
cmp.l #MINSTK,d2 * try (free space + __STKSIZ)
bge setstk * if < MINSTK
```

... et cetera. The code goes on to reserve the actual stack space by
figuring _STKSIZ into the amount of memory saved before calling
Mshrink. Then it sets the stack pointer accordingly. This is a
different method than is used by some of the alternative startup
modules I've looked at (I don't have sozoinit.s, so I can't check).

Where does _STKSIZ come from? It's in its own little module at the
tail end of dlibs.a, where it is defined as 4096L. But it is linked
into your program ONLY if you don't define the variable yourself.
Therefore you need to create a module containing the following line:

```
long _STKSIZ = (16*1024); /* 16K stack */
```

Note that it's not ``extern long'' because that would cause the dlibs
stksiz.o module to be linked. You don't want that.

Add your stksiz module to the link list passed to cc (or in your
makefile). Then your stack problem should go away (possible unmasking
other problems, but that's the next chapter.)

>around by apple thats ok...

I wholeheartedly disagree. Hardware problems aren't a problem, as if you
have a local dealer, or any Apple dealer, he MUST provide support for hardware
and software training/consulting.

Then of course, whats $700 hundred bucks when one can cash in on a
software market so huge its in the Hundreds of Millions of dollars
per year. Whats the ST market? A few ten thou here and there?

As for tools, the Mac has much better software tools than the ST or TT
will even SEE in thier lifetime, let alone waiting for someone from
Atari to provide good compilers, system software.

> EARL C. POTTINGER (Amiga Lover, Hacker & CyberNerd)

If "WHATEVER" includes MiNT, you're wrong -- MiNT already forbids
writing to files opened read-only. I suspect that Micro RTX does
the same thing. So there is *some* incentive for developers to fix
their broken programs. (And also at least one way to test to see
if a program has this problem -- if you run it under MiNT with
debugging on, you'll get a message from the kernel like
"pid xx: write to a read-only handle"
if the program does something as obnoxious as this).

(I haven't actually seen many such programs -- I doubt it's a very
widespread problem. On the other hand, I do understand that Atari
has to be more cautious about this than I do; after all, anyone who
uses MiNT is presumably fully aware that not all TOS programs are
MiNT compatible, whereas it's a nasty surprise when your favorite
program breaks under a new version of TOS.)

> the ``proper'' startup module for dlibs.

Overnight I snagged sozoinit from the archives (all hail BART!) ...
and if that's what you're using, then the value of _STKSIZ has nothing
to do with your stack.

In sozoinit.s, the values are hard-coded:

```
.ds.b 6144 * 6K stack size
; change ^^ to something bigger if you want
_stackbottom:
.ds.l 1
.text
__main:
lea __main, a5 * Compute basepage address
suba.w #$100, a5 * subtract size of basepage
lea _stackbottom,sp * set up our stack
```

Note that if you want to use sozoinit.s, you should fix the part where
it tests the parent basepage pointer to determine whether it's an accessory
(see previous discussion in this newsgroup) and you might want to add
paranoid stack checking (see dstart.s).

To link sozoinit.o instead of dstart.o with standard cc.ttp, you have
to directly call the linker:

```
cc -O -c sozoinit.s yourfile.c
ld -o yourprg.tos sozoinit.o yourfile.o \lib\dlibs.a [and any other libraries]
```

Couldn't have said that better. This bug, however, is only part of
the problem. IMHO, the whole GEMDOS in its present form is a big
problem when multitasking is involved.

Source record: 47457

I think the reason for Atari's reluctance to fix bugs like this is that they took so much flak over the STE.

Hackers whose cute little programs had blithely assumed where the screen RAM was and where the ROM was and so on suddenly stopped working. Who did they blame? Who did the MAGAZINES blame? Atari.

Most of the magazines did, however, say that if the developers had been given more notice of the changes and if machines had been available to more people for longer before the actual release, it wouldn't have been a problem.

Personally, I suggest:

1. Announcing exactly what bug-fixes are going to be made one year in advance. You don't need to announce radical improvements to TOS, just the bug fixes which might break existing software.

2. Providing little PD patch programs so that developers can see if their programs will fall foul of the fixing.

3. One year on, fixing the bugs. Ignore those who whine.

I'm currently vaguely considering a TT to go with my two STs, or maybe a 68030 accelerator. But if Atari's not going to fix known bugs in TOS, I'll shift to another platform entirely.

It sure does work. If your ST doesn't have an RF modulator built-in this
was made for you. However, as most people know TVs aren't as good
resolution as monitors and using med. rez on my TV at least is nearly
impossible. I guess it depends on your TV. Low rez is OK though.

There is no bflags field in the boot sector, only in the BPB. The disk
driver is responsible to set this at its need, and GEMDOS *do* care
about it. The BIOS floppy driver has no way to find out which FAT
format the disk uses only by looking at the boot sector, so it assumes
12 bit FAT, which is standard MSDOS format

Message-Id: <91Jul18.085110ndt.108851@garfield.cs.mun.ca>
Date: Thu, 18 Jul 1991 08:51:06 -0230
Status: R

I have an ICD FAST Hard drive with two mechanisms inside, a 32 meg and a 40 meg.
A couple of months ago, sometimes when I'd try and access one of the drives
(always the same one), it would lose power, and you could visually hear it
spin down, and then sort of restart. Sometimes this would persist, and the
system would crash, other times it would come up to speed and work ok.

Gradually this problem got worse and worse. In fear it might be the mechanism,
I switched the two mechs in the case, now the problem began to occur on the
other drive. Therefore I concluded it was the powersupply (I beleive it is
115 watts?). I replaced the power supply with a similar one and the problems
disappeared. (Great!)

Now a couple of months later, it is beginning again. I can't afford to be
replacing powersupplies every couple months! Do I need a heftier supply?
Is there a simple part of the present supply I can replace? Shouldn't ICD
ship the damn thing with a supply capable of driving two drives if the case
fits two drives? Should ICD do something about this? Is this a know problem?

I've got a BIG report due in the near future, and I dread the thought of it
without a harddrive!

Any input will be greatly appreciated!

Thanks

Sorry, there is no such flag in the boot sector. It's only in a BPB.

Geez, I wonder where I got sozoinit.[so] from then. I don't remember putting anything that didn't come in the latest Sozobon distribution into the \sozobon hierarchy (except for the microrts library and a library of mostly window routines, which I explicitly know about).

> Here's what happens.
>
> Where does _STKSIZ come from? It's in its own little module at the

> Therefore you need to create a module containing the following line:
> long _STKSIZ = (16*1024); /* 16K stack */

Which is exactly what I did. When I saw the explicit ".dc.b 6144" in sozoinit.s I started having doubts about whether _STKSIZ was getting linked in automatically and allocating memory, instead of needing the library routines updated before compiling the target. And I either wasn't using -v or wasn't paying attention to what was being linked in as the startup module (concentration begins breaking down as it gets later, and later, and later . . .).

> Note that it's not ``extern long'' because that would cause the dlibs
> stksiz.o module to be linked. You don't want that.
>
> Add your stksiz module to the link list passed to cc (or in your
> makefile). Then your stack problem should go away (possible unmasking
> other problems, but that's the next chapter.)

Actually, I'd been going with "long _STKSIZ = 16384" all along, but I hadn't unpacked szadb1_4 till last night, so I was hoping that it was simply a problem with the startup module (I just couldn't decide whether it was sozoinit or dstart getting linked in) and its handling of stack allocation. It was the first time I'd used the compiler to put something substantial together and I wasn't trusting it 100%.

Now it seems I'll have to trust the compiler a little more and the Zoo 2.1 sources a little less. And use szadb, I guess.

2968. Beta Testers Needed

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-18 14:17:17 UTC
From: uace0@menudo.uh.edu
Message-ID: <1991Jul18.141717.7233@menudo.uh.edu>
Source record: 47453

Double Click Software is looking for beta testers for a soon-to-be-released professional game authoring system.

Interested parties should send email to:

uace0@menudo.uh.edu (that's a zero - uace0)

Do not reply in this newsgroup, we will ignore it. Send email only.

Would be testers _MUST_ :

1) Have programming experience in GFA BASIC, 'C', or assembly.
2) Have _serious_ time to dedicate to testing (this is an *extensive* system).
3) Have game design knowledge (would be nice) or really want to write a game.

SERIOUS REQUESTS ONLY.

Include with your request:

Your name.
A telephone number (in case reply mail bounces back).
What programming experience you have.
What programming language you use (and what package you currently use).

Thank you.

Double Click Software

Hello David,

the Hsync & Vsync -Signals of the old mod are not very stable.

> I would appreciate any advice from people who have done this modification. As
>a carrot for Karsten Isakovic and/or Stefan Hartmann I plan on supporting the
>OVERSCAN at work if I can get enough test machines running flawlessly. (yes I
>eventually would like to get a couple of the AutoSwitch OverScans)

The US distributor of AutoSwitch-OverScan is RIO Computing in Las Vegas. I
don't know the price (RIO didn't order up to now...). In the Uk AS-OS is
distributed by Summer Workshop.

Greetings,
Karsten

2970. Programming with GEM (I need Help)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-18 14:27:07 UTC
From: D.M.Johnson@newcastle.ac.uk
Message-ID: <1991Jul18.142707.7554@newcastle.ac.uk>
Source record: 47455

Hello,

I have been doing some programming with GEM using Hisoft Power Basic, and have managed OK (due to the fact that the run time system does most of the work for you). How ever when using the command: WINDOW FULLW, I thought to my self how do I do this in another Language, or by myself without the run time system doing it for me.

For those who do not know WINDOW FULLW provides the user with the complete screen as a work area.

So I sets to work, I create a window the size of the full screen (640 x 400 in mono) and messed around with the aes graphic commands, but I could not get it draw in the area were the menu bar is expected. I have seen many programs with the full screen accessable (eg art programs) so it must be possible, so in order not to re-invent the wheel could some one tell me how to do it.

Hope the above is clear

Dave J

2971. Re: Problem w/ TeX 3.1 at atari.archive (was Re: getting TeX up and running on your ST)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-18 16:32:38 UTC
From: ralph@laas.fr
Message-ID: <RALPH.91Jul18183238@orion.laas.fr>
Source record: 47540
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have uploaded to atari.archive a corrected version of BibTeX
compatible with the new TeX 3.1 distribution. Credit goes, of course,
to Frank Ridderbusch for recompiling it! The difference is that it
accepts a TEXINPUTS environment variable compatible with TeX 3.1/LaTeX:

setenv TEXINPUTS '.\acm;.;e:\tex\inputs\local;e:\tex\inputs'

Dont forget that in both versions your *.bib files are looked for in
the BIBINPUTS path environment variable analogous to TEXINPUTS.

Cheers,

Well, I'm not really too excited about this. I'm just left with this paranoid wondering of how this stuff sozoinit got into my \sozobon hierarchy if it wasn't part of the original distribution and I didn't put it there. If it wasn't for sozoinit I would have jumped on dstart right away (since there would have been nothing else trying to look like a startup module in my \lib). A good reason to use cc -v . . . and watch what goes on a couple of times . . .

2974. Help! How do I Use PC_DITTO with a megafile 30?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-18 18:39:21 UTC
From: jds20@ruts.ccc.amdahl.com
Message-ID: <7a=2028T09rT01@JUTS.ccc.amdahl.com>
Source record: 47501

When I start up PC_DITTO it recognizes that I have 3 hard disk partitions available but when I type the command "DIR C:" I get the message "Divide Overflow".

It seems that PC_DITTO does not recognize ATARI's new hard disk format. If I reformat my megafile 30 as an SH204 using the 1986 version of HDX then PC_DITTO recognizes the C drive and works fine. The only problem is that now I only have 20 Mb available on my 30Mb drive.

Does anyone know how to get PC_DITTO to work with the full 30 Mbytes?

Thanks, Doug Smith (jds20@ruts.ccc.amdahl.com)

2975. Can't get G_PROGDEFs to work! (G_USERDEFs)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-18 21:56:14 UTC
From: cmedley@wam.umd.edu
Message-ID: <1991Jul18.215614.22736@wam.umd.edu>
Source record: 47459

I'm trying to write code to handle a group of programmer defined objects in a GEM resource tree, and the trouble is, my drawing code is being called but the parameters are not being passed properly to it by the AES.

The Tim Oren ProGEM columns said that there would be a 32 bit address (pointer) to a PARMBLK structure on the stack, but after checking both the supervisor and user stacks, I don't see how it could possible be right, since the SSP is pointing at some ROM address (in this case, 0xFDDED4), and the USP is pointing at 0xAC90, which in turn points to what appears to a data structure that cannot possibly be a PARMBLK for the G_PROGDEF objects.

Can anyone, anywhere on Earth, help me? :)

2976. Need a good book on the ST

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-18 23:12:23 UTC
From: cpmurphy@vax1.tcd.ie
Message-ID: <1991Jul18.231223.1@vax1.tcd.ie>
Source record: 47460

[I am posting this for Thomas who has temporarily lost news access.
Please MAIL replies (I have set the reply-to field to be him).]

I have a request for those in ST land (c.s.atari-st). Any help is gratefully
accepted:

In a nut shell, I am looking a good technical reference text for the
Atari ST computer. I am working for a newly started games company in
Ireland and am responsible for the Atari format of a new game.
Unfortunately we have no suitable atari texts.

What I'm looking for is a LOW level and DETAILED reference book on the
Atari ST hardware and its programming. Basically I need to know how to
handle disk drives, graphic output, keyboard and other I/O devices without
the aid of an operating system. I need to hit the metal I'm afraid.

I was told of a text by ABACUS called "Atari ST Internals" that is
supposedly the best. However, after much searching, I find that this book is
not longer in print (just my luck). So, my two questions are:

i. Is there anyway I can get this book second hand?

and,

ii. Can anyone recommend an alternative text(s) that is as good
or better. And if so, where can I buy it(them).

Disclaimer: I don't read this group (though I suppose I'm going to be in
the future), so apologies if this has already been discussed.

-Thomas.

2977. STe/Mega ST clock question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-19 00:05:59 UTC
From: pv@polari.UUCP
Message-ID: <4809@polari.UUCP>
Source record: 47461

I've been informed from a certain Atari ST developer that I must purchase a used Mega 4 ST for the hardware unit they sell because there is a clock difference in the new STe line that causes problems in this developer's hardware/software. This is news to me. It also puts a bug in my plans as Megas aren't as common as the other ST models. I'm not sure, but seemed to be something about crystal speed difference between 30MZ and 31.2? Has anyone heard of this or can confirm/deny it?
Thank you.

GC> Bah hah ha ha ha. I almost dumped my brunch when I read that.
GC> Please, people, if your going to write jokes keep it out of
GC> comp.sys.atari.st OK? This is not the appropriate newsgroup.
Why? I wasn't joking.. As far as I have seen I still think for the average Joe
the Atari support is much better then any other computer..
(Except maybe the Amiga. Last I heard they had a simular program but I also
have heard they have a 1-800 number.. Although you CAN call Atari
if your a developer and get help.. I have called myself... Just not on a
1-800 number..)
GC> I wholeheartedly disagree. Hardware problems aren't a problem, as if you
GC> have a local dealer, or any Apple dealer, he MUST provide support for
GC> hardware
GC> and software training/consulting.
Hmm, I wasn't talking about Hardware support.. I was talking about development
support..
GC> Then of course, whats $700 hundred bucks when one can cash in on a
GC> software market so huge its in the Hundreds of Millions of dollars
GC> per year. Whats the ST market? A few ten thou here and there?
Yea but how do you expect someone to start out? On a Mac you certainly can
not start programming anything serious without but about 10 different books..
Expect to fork no less then $2000 worth of hardware (And this is a bare bones
system really.. You could "get by" on a mac classic with a 20 megger but then
what do you use to print on.. Oh of course.. An imagewriter.. Laser printers
are out of the question..)
As to software.. You either spend the $200-300 for the language and spend
MONTHS learning the OS or you can spend a couple $1000 in software tools..
(Without the tools and without skeletons or something to start from expect
atleast double the normal time to figure out the environment..
These are not cheap to get...)
Of course you COULD spend the $700 IF your planning on getting a commercial
program out in two years.. Never mind if your a gov't or large company doing
inhouse software developement for inhouse usage.. You won't get ANY support..
And to get actual support you must pay ungodly fees to access applelink where
you MIGHT get help within 48 hours..
GC> As for tools, the Mac has much better software tools than the ST or TT
GC> will even SEE in thier lifetime, let alone waiting for someone from
GC> Atari to provide good compilers, system software.
Ataris don't NEED extensive tools as the mac does.. You can just hack it
altogether... ;-)

My experience...
Been using Genie for 1.5 years now.. I see people get helped with their
questions normally within 24 hours with very good examples etc..
I have the atari developers docs and full developer status..

Unfortunatley due to time restraints (Full time student.. Working on a comp. science degree, full time job, run a big bbs, and spend lots o'time with my girlfriend..) I havent done as much as I would like to do.

On the mac.. Took me better then a year and a half to make a scheduler program and a transfer system. (I created a system to link our Atari 800xl's in our lab to the Macs over the network. Works well. We have a simple one way network sending information in slow xmodem type transfers from the lab controlers (namely the 800xl's) to a mac that inserts the information into a database or spreed sheet.) MOSt of this due to making the stupid things work together.. (Has a Cdev, a background program and a normal program all running.. I KNOW it wont run under system 7 right away.. I had to make the scheduler program run the transfer program and the mac has no way of doing that that is supported throughout the systems..) Since I work for a city govt and all the software development was suposed to be inhouse they said no to support unless we were gonna release a commercial program. And the city didnt understand asking for

2979. Monitor problem?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-19 06:21:00 UTC
From: JJL101@psuvm.psu.edu
Message-ID: <91200.022100JJL101@psuvm.psu.edu>
Source record: 47463

Anyone help me on this one? -> I have been getting bands of black lines
that flicker on and off on my monochrome monitor and a 1040ST. They sometimes
get so that they fill the entire screen and turn it all black, but fade in and
out at seemingl random times. Then a while ago then entire screen turned
completely pitch black. Nothing anywhere. I switched to TV for color for
a bit, and retried the monitor, and now it appears to be back to normal.
The TV never has this problem. At first I thought it was interefernce
perhaps, then i heard it may be the video chip?, and now with the latest
incident that seems unrelated to the black lines,(this was a total screen
blackout with no fading out like normal) I think it may be the monitor
itself. As I sit here now, everything is perfect, no lines, nothing.
Looks like a new monitor.
Can anyone give me advice on what I should check to see what may be
causing these problems? I am not afraid to open the machines up, and
with my old 520, I have opened them up and added memory etc, but in this
case I am not at all sure what I should be looking for or what I should
be checking.
Any help would be appreciated!

2980. Re: ICD faST Hard Drive problems!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-19 06:38:45 UTC
From: lahtinen@funet.fi
Message-ID: <LAHTINEN.91Jul19083845@nic.funet.fi>
Source record: 47462

Yes the original ICD power supply is quite weak (I think in theory only about 40). It seem to work with two Quantum drives, but some other makes are too power hungry.

I do not have any problems as I have 150W PC supply...

lahtinen@gideon.fmi.fi

PS. Actually I have a problem with the power supply - when I turn on my printer or table lamp my Atari resets. (The whole system is powered by that 150W switching power supply). I know I need some kind of filter or similar, but I do not quite know what happens if I add a big capacitor after a switching power supply.

2981. Info needed on HD specs (power consumption)

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-19 11:19:31 UTC
From: tdrga@ccwf.cc.utexas.edu
Message-ID: <52560@ut-emx.uucp>
Source record: 47466
Cross-posted to: comp.periphs,comp.periphs.scsi,comp.specification,comp.sys.atari.st.tech,comp.sys.mac.hardware

(Sorry about the range of crossposting - I need an answer quickly)

I am adding a Seagate ST296N SCSI drive to my Atari ST system and need some specs on it and the Syquest 555 drive that I already own.

I originally purchased the Syquest drive as part of a drive/controller/ power supply/case deal. I am now going to add the Seagate drive to the case and power it from the power supply. The place I bought the Syquest drive from did not include any info on the power supply, but on the rectifier there is an indication of '60 W 50/60 Hz 115/230 VAC.'

I need to know the power consumption on the drives so I can figure out if I'm setting myself up for a fried power supply in the near future by running both disks from it. It seems to me that a 60W power supply is rather puny, but that's because I don't have any experience with putting a drive system together.

Please email all responses... I'm wasting enough bandwidth as it is.

Thank you,

Todd Drga

From: Roger.Sheppard@actrix.gen.nz
Message-ID: <1991Jul19.121056.7803@actrix.gen.nz>
Source record: 47467

Can some one help me with the Supra Clock Problem,
this is the one with the Clock Chip (RCA) draging down
the battery.

I read some where that Supra was replacing faulty Clock chips.

But I rang Supra to find out that I would have to send
my Host Adapter back for them to replace the Clock IC,
with a Dalas one.

This was not just a plug in job, traces have to be cut, etc.
I asked them if they could give me the details,
so I could do it myself, I told them that I was a competent
Computer Engineer, no way and could not even give me the
Dalas clock chip part No.

So is there some one that can give me the Part No.
of the Dalas Clock Chip, and also if Possible the changes
that where made to fit this device..

Note: I also fould out that there software version 4.01,
does not support BGM

From: Roger.Sheppard@actrix.gen.nz
Message-ID: <1991Jul19.130425.18035@actrix.gen.nz>
Source record: 47468

If you are using a STE on 230/240 volts AC, and have
a Phihong (Taiwan) made Power Supply.

There is a small problem that can cause the Power Supply
to die.

R1 (470k) is a Start up resistor for the inverter,
this can go OC, as it is not rated for the 380v dc,
that is fed aross it,
Replace this Resistor for a 1/2 whatt type,
about 10 mm long, 3.5 mm wide.

** Atari Mega File 44 **.

Are there many problems with the door on the Cartridge, not opening,
caused by a faulty/bad design lever that opens the door, this caused
the heads to come into contact with the door and end up bent.

So far I know of 2 of these, a repair centre stated that this is a
common problem.

The Atari Dealer here, refused to recognise this as a problem,
and refused to replace the drives, claim that they only have
a 90 day warranty.

... but the FATs are both by the same piece of code located somewhere in
the depths of GEMDOS. The driver is only responsible for block read/writes.

Bit zero of the BFLAGS field in the boot sector should tell whether to use
12 or 16 bit FATs. But as Claus Brod said, 16 bit FATs seem to be impossible
on floppy disk. Don't ask why ... the GEMDOS FAT evaluation routines don't
seem to be very well programmed. :-(

Actually, there are some pretty darned good tools available for the ST and TT (e.g. gcc and the other gnu stuff) at very reasonable prices (e.g. free). Yes, they're not as user friendly, but they *are* extremely powerful. For serious development work, and for experienced programmers, these tools are fine. (I would agree that "casual" programmers may not find them as nice as what's available on the Mac; but I'm not a casual programmer, and I don't want to have to wrestle with my compiler to get it to do what I want).

|BTW: What does this
|strange magic 'F0AD' in AHDI mean? Are there hidden meanings behind
|other system magics?

Knowing Landon's propensity for putting, uh, interesting things in
the TOS code, I wouldn't doubt that F0AD stands for something...
Let's just say the last two words are ...and die.

There are plenty of other interesting magic values, for example,
resmagic (which validates the reset vector) has the value of pi
when hex-dumped, i.e. $31415926.

|PS: My auntie recently was bitten by a ... - oops, wrong movie

Yes, well MACCEL's cookie would be LLAMA if it weren't so hard
to put in hex <chuckle>.

BTW, to answer Julian's question, the STE Addendum (where the cookie
jar is documented) doesn't require that cookies be printable
when ASCII dumped, it only suggests that. It's a good suggestion
though. Since CPX IDs *must* be 4 ASCII characters, we may as well
be orthogonal, no?

MACCEL was probably the first program ever to use the cookie jar.
It was written before even the preliminary cookie jar documentation
was passed along to developers. So... there's my excuse ;)

2990. GSTSHIFTER problem good (old ste) chip ID num?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-19 16:52:21 UTC
From: pegram@kira.UUCP
Message-ID: <1991Jul19.165221.4805@uvm.edu>
Source record: 47473

I have the problem that Lars Erik Osterud has posted about here for
new mega STes and Stes (I have a new Ste). Lars didn't provide the
necessary chip numbers for me to get a *correct* replacement from Best
Electronics (hey the warranty went when I put in the 4 1meg chips 8-).
Does anybody know whether this is the new Shifter chip and what the g
ood and/or bad chip numbers are?

Assuming that the "GSTSHIFTER" is the new Video shifter chip,
and no one posts the chip numbers, I have a request:

If you have an older Ste that flips Mono screens properly (no wrapping
left of the screen, try a Degas picture cycling program), has *no*
static in DMA sound (try an STe noisetraker program - LarsErik wrote
one that shows the noise problem), and displays Spectrum 512 pictures
properly, please open your machine up and look for the chip number of
your STe Shifter chip. NOT the U (board) number but the one on the
chip itself. Lars' U numbers were U401 for his '89 STe and U502 in
his new Mega STe, hope this helps you find the chip, but U numbers
vary tremendously with each board revision 8-). Unless I miss my
guess, it *is* socketed and should be in its own video rf shielding
box inside the regular shield of the STe. Post the number you get and
we'll see if substituting your version of GSTSHIFTER for mine really
solves this problem. I guess the STe DMA problem has not gone away,
just moved into the sound and video area 8-(.

My neighbor had a VideoKey so their kids could play games on the TV. It works well, tho not any better than the rf port on the 520 (they claim it looks better since it's straight composite-output, but it didnt't to us).

80 column text on a tv is legible for the most part, but some letters are confusing/hard to read. It is, tho, the ONLY computer I've EVER seen that is at all useable in 80 col. on a tv. They designed the pixels in med. res. shapedlike a vertical rectangle (the monolith!). On a tv it's readable, and on the Atari's CGA-pixel color monitor, the text looks as good as EGA on a PC. THat's a big reason why I prefer it over the Amiga, too.

Anyway, the VK got zapped by lightning. With a new one costing $80, they decided to invest the $$ in a used color monitor instead.

Someone wrote recently that cables were the cause of a high percentage
of problems with hard drives. I have no large mass of data from which
to make such a statement, but I can add my own anecdote.

For a while, I had a problem with my ICD FaST Drive (48 Meg) similar to
the one described above. Several times I looked inside and poked
around, not really doing anything. I did no soldering or desoldering.
What I did do the last time was to disconnect and re-connect every
connector inside the system. Now I conjecture that I had some
corrosion that was limiting current flow. I suspect the connector
from the power supply to the internal cable going to the drive.

I had trouble with poer connectors in my hard drive a while back
and what I found was that the 4 pin connectors were very badly designed.
The standard connector has 4 pins, three of one sex and one of the other
to maintain alignment. These are simple ridged tubes that slip into each
other, but the plastic housing around them is so loose as to allow one
or more pins to be pushed back into the housing and not make a good
electrical connection. Check each connector carefully to make sure
each pin is actually fully connected with it's mate.
Once I found the badly connected pin, I've had no trouble for over
1+ year.

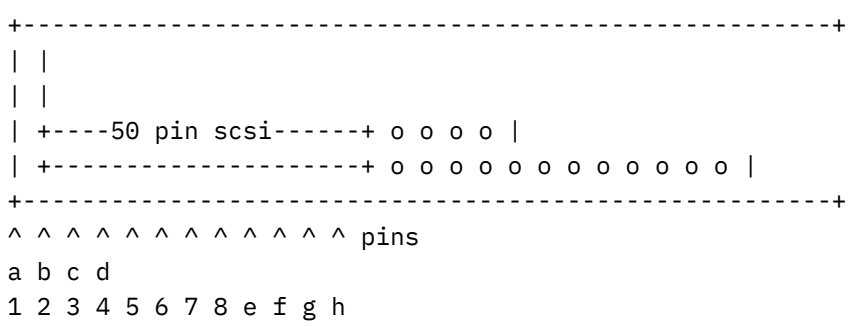
A friend of mine and I just went to a ham-fest and bought an Imprimis 94211-106 to use on his Atari ST through an ICD SCSI host adapter. We couldn't get the ICD software to recognize the device on the SCSI bus. What we would like to know is, what do those configuration pins on the back of the drive mean? Below is a rough sketch of the pin layout.



The drive comes with pin 2 & 3 connected. When we turned on the drive, the front LED stayed on for about 10 seconds and went out. Nothing else happens then. On a Seagate ST157N, it normally turns on for a while and shuts off. When the system checks the SCSI bus for devices, the LED on the ST157N would flash. Not on the Imprimis.

We would like to set this Imprimis up as SCSI device 1, no parity. Will anyone be able to help us? It's supposed to be a 109 MB embedded drive.

Well, if you have the computer well ventilated (and maybe a fan
blowing air through it),it should work ok. Remember - all those 24 hour
BBS's have to stay on day and night, many of which are runon ST's.
Why would you want to leave it on all the time anyways?

Are you running a program on it that needs to be up all that time? I run a BBS on my Mega ST it acts weird after running for a few days at a time (I took the BBS down to write a paper on WordPerfect, and my Wp locked up while I was typing... I never had ANY problems with the WP software before that. I don't know if it was just a coincidence, but leaving the computer on for mso long might've had something to do with it.)

On a 1040ST, without a fan built in, there could also be overheating problems (I used to run my BBS on a Commodore 64 and it burned out every 2 months or so, because it got so hot)

3008. ST power supply question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-21 22:02:07 UTC
From: tdrga@ccwf.cc.utexas.edu
Message-ID: <52681@ut-emx.uucp>
Source record: 47491

I finally opened my 1040STF last night for a much needed cleaning and decided to check the power supply since I thought it was running a little hot. Using a digital multi-meter, the DC output from the PS were a bit low. Instead of 12vDC, i got something like 10.4 and instead of 5vDC, I got 4.4 or so.

Is this a problem? I may end up getting a 200w PS and running the computer and both my hard drives off of it, just to be safe.

Thanks,

Todd Drga

Changing a fan once every few years is no big deal. Changing a knackered
hard disk with little or no advance notice is no fun. It's a real pity
that manufacturers of hard disk systems are too busy selling them to bother
with designing in a standby mode. I would like to see a system that powered
down the hard disk after a specified period of inactivity, powering up again
on demand. Autopark would be best. This would also reduce the risk of damage
by earthquake on a BBS (or any other) system during periods of inactivity.

3011. Programming the Blitter

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-22 00:28:50 UTC
From: redmond+@cs.cmu.edu
Message-ID: <1991Jul22.002850.19081@cs.cmu.edu>
Source record: 47497

Is it possible to expilcity program the blitter (in either C or assembler) ?
Or can it be only used via GEM call, and Line-A etc.?

Could any one give me any details, or tell me where details are to be had?

Basicly I know I've got a blitter in my STe, and it supposedly magicly
increases the speed of graphics operations, but that's about it!

Any help would be much appreciated,

Thanks in advance,

Red/.

3012. Re: Switching on/off

Source record: 47492

Atari ST's are so robust that they can operate for months continually.
The points to remember are:
(1) are you not wasting electricity?
(2) If the picture of the monitor does not change for half an hour, the monitor will 'burn', i.e. you will have eternal dots on it.
(3) the bearing of hard drives and fans do not wear. They are designed to last for five years if my memory doesn't fail me. If you turn off the hard drives, you will be wearing the mechanism of hard drives (the spin up is such a stressful event). Most of the hard drives whose capacity is over 2 gig bytes are not turned off once they are installed.
(4) the big aluminum electrolyte capacitors are particularly vulnerable ot initial power-on phase. They are also vulnerable to heat. Buying a good Japanese capacitors will help (105 degrees stuff, not 85 degrees. I always buy Nichicon). When capacitors got bad, the power supply will fall (say, from 2.5 amps to 1.5 amps), and if the 5V falls to 4.7 volts the ST is known to misbehave.
Cheers,
Y.T.

3013. Re: Switching on/off

Source record: 47493

Also note that the aluminum electrolyte capacitors (the big cylinders) do not last long. The life span used to be two years. There have been a great improvement in their quality in the last two years, which has enabled the life span longer (they can stand the histerisis much better now).

Also note that though Atari ST's are designed to operate in the ambient temperature of less than 35 degrees centigrade, the temperatur of the room should be kept less than 30 degrees to be safe. If you buy a top quality fan, it will beep when the temperature has gone too high or if it has broken down. This kind of fans are used for expensive equipments.

>but the parameters are not being passed properly to it by the AES.

USERDEF code is declared as

int func(PARMBLK *p) { ... }

in C.

So AES does something like this:

pea parmblk
move.l ucode,a0
jsr (a0)
addq.l #4,a7

Since jsr pushes a 4byte retaddr on stack, you have to use

move.l 4(a7),... to fetch the address of PARMBLK.

Hope that helps, Bjoern

4.4V is not within specification for 74series LS-TTL chips and most likely the
Atari custom chips are within the same power supply tolerances. LS-TTL requires
5V +- 5%

3016. STe file selector

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-22 08:03:40 UTC
From: jansteen@cwi.nl
Message-ID: <jansteen.680169820@piring.cwi.nl>
Source record: 47499

Today I noticed that when giving a relative path to the file selector
of the Atari STe it's impossible to do more "cd .."'s (using the close
box of the window) than the directory where the relative path started.
This has to do with the way the system figures out the parent directory.

An example to illustrate what I mean:

```
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-= sample.c =-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
#include <stdio.h>
#include <string.h>
#include <aes.h>

#define PATHLENGTH (64+1)
#define FILELENGTH (12+1)

main()
{
char path[PATHLENGTH+FILELENGTH];
char file[FILELENGTH];
int button;

(void) sprintf(path, "%s\\%s", ".\\MISC", "*.C");
(void) strcpy(file, "FILE.C");

exit(fsel_input(path, file, &button));
}
-=-=-=-=-=-=-=-=-=-=-=-=-=-=-= sample.c =-=-=-=-=-=-=-=-=-=-=-=-=-=-=-
```

This will result in the file selector showing:

```
Directory: .\MISC\*.C
Selection: FILE.C
```

When applying the "cd .." button of the file selector it will show:

```
Directory: .*.C
Selection: ________.___
```

So, it seems that the system code performs the "cd .." command
by stripping *one* directory from the current path. However,
the used algorithm doesn't make sense in this case.

My question:

Should one only supply full pathnames to the file selector,
or should the described behaviour be considered a bug?

Three notes:

1. The used algorithm (stripping instead of executing "cd ..") does
make sense for file systems which support symbolic links. So, it
is not necessarily a bad algorithm to use. Subject of discussion
is the *way* the system strips.

2. The current working directory of the test application was below
the root of the file system.

3. The above program might perform differently on older TOS systems.

3017. How to daisychain Atari Megafile 20s?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-22 11:13:15 UTC
From: grahamt@syma.sussex.ac.uk
Message-ID: <5604@syma.sussex.ac.uk>
Source record: 47502

A colleague of mine has used a Megafile 20 for a number of years (it might be an SH205, but I think they're the same). He has now inherited another Megafile 20 from another colleague and wants to daisychain them, preferably without losing the data on either drive. Both drives are out of warranty, and both were formatted with Atari HDX v2.something. I'd just like to ask a few questions and check the best way of doing things:

1. DIP switches. I think Atari HDs are normally set to 0. So we just open up the second drive and set it to 1, yes? That's unlikely to clash with Atari laser printers, as they are normally set to 5 or 7, right? Anything else it might clash with? How accessible are the DIP switches?

2. We'll remove SHDRIVER.SYS (or whatever the autoboot file was called in version 2) from the first partition of the new drive before starting. Is that all we need to do in order to allow the old drive to autoboot without getting confused?

3. TOS/GEMDOS etc. should recognise the new partitions and give them drive letters which follow on from the last logical drive on the first disk (assuming they are all GEM partitions), yes? We'll have to install them on the desktop of course.

Sounds suspiciously simple. What have I left out? Where am I going wrong? Will we have to reformat/repartition?

This will be running under TOS 1.0. Yes, I know 1.4 would be much better, but apart from the sorts of problems fixable with FATSPEED and the like, is anything likely to break which would not with 1.4?

Thanks for any help you can give.

Graham

>12 or 16 bit FATs. But as Claus Brod said, 16 bit FATs seem to be impossible
>on floppy disk. Don't ask why ... the GEMDOS FAT evaluation routines don't
>seem to be very well programmed. :-(

Daniel, there is no BFLAGS field in the boot sector. The BFLAGS field is
provided by the getbpb() function which in turn is handled by the
appropiate disk driver. This means that each driver decides whether
a drive that it controls uses a 12 oder 16 bit FAT. The low level
BIOS/XBIOS floppy driver assumes a 12 bit FAT. There is nothing
which keeps a programmer from adding a new floppy driver that allows
16 bit FATs. In fact, this could even be done using a very small TSR
that hooks into the hdv_bpb vector.

You could say a lot of quite unpleasant things about GEMDOS, but it
has no problems telling 12 bit FATs from 16 bit FATs. To sum it up:
It's not a GEMDOS bug. It's not even a BIOS bug. It's a feature.

> Where can I get one at a very good price? (what is the price?) [for a <40 meg
>unit]-
>-
>Ken.

I was able to take the following approach. I bought a used 20 Macintosh drive ($100 CAN) and bought an ICD host adapter, mail-order, to run it. Although the adapter handles many, many different controllers, it didn't handle the one in the Mac drive and ICD told me they never would (because of the custom control codes used) So I also bought a SCSI controller board from ICD. The system ran well on the bench, but.... now the packaging was all wrong. I needed to mount one of the boards on the outside of the original drive case and extend the case cover, but... before I got the cover built , I overdrove the power supply and blew it's fuses.

I now have a custom case, overated power supply, cooling fan, 20 meg drive, controller and adapter boards and room for another drive unit on my desk. Don't get me wrong, it was a learning experience, and I now have a reliable hard drive for the ST, built for about $300 CAN.

The bottom line, if you build it yourself, what you save in dollars, you MUST spend on patience! 8^)

>about 10 mm long, 3.5 mm wide.

Anyone know if some machines shipped to North America have a similar problem?

Here's what has happened with each of the last two STE I have had. After being, on for a while, the machine sometimes terminates in a multitude of bombs. So, after I power down and wait 30 seconds, I try again.

The screen turns white, but the floppy drive never kicks in. If I leave the machine off for a good number of hours, it usually will work again.

Could this problem be related to the power supply?

How (and where) can one find a replacement power supply. And, how easy is it to replace?

Thank you,

Erik Johnson

3023. HELP!!! Sozobon C!

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-22 16:01:25 UTC
From: aa400@cleveland.Freenet.Edu
Message-ID: <9107221601.AA09169@cwns10.INS.CWRU.Edu>
Source record: 47506

I am learning C from C-Manship complete, by Clayton Walnum... I am trying
to use the sozobon c compiler, but I am having a lot of trouble with it.

I have all binaries in sozobon/bin, all lib files in sozobon/lib, all
include files in sozobon/include... My C programs are in sozobon.

To compile a program, I use a pd CLI accessory, because I can't get anything
to work from the desktop.. (Parameters..) Anyway, if I simply type the
filename of the C program I want compiled with cc.ttp by

cc.ttp program.c

I get a "File suffix:"program.c" not known....

I did get it to compile SOME programs by simply placing a quote in front
of the filename, by cc.ttp "program.c

The problem is, for some reason the compiler doesn't recognize some functions,
even though I remember to include the header file... for example, if
I #include <stdio.h> and #include <osbind.h> I get an undef _Random and
undef _abs.... (I am using the functions in the program..)

I checked through the osbind header file, and Random is definitely defined
as xbios(17).. I am not sure about abs, so I went ahead and included
math.h, but that didn't work either! Sozobon C has to be more complete
than that... I know it is!

Please tell me what I am doing wrong... I am not used to using a cli, but
I have no idea how to use cc.ttp with the desktop thing...

Thanks in advance.

>Simply removing the driver might cause problems.

Hey there,

My friend has a Supra 30M HD in the 20M case and I have a Megafile
30. Could we perform the same type of operation on one of our drives
and then copy files between them? They are in 4 partitions. This would
obviously need to be a reversable process, ie. the .sys driver would need
to be put back on, but can this be done without wiping out the drive.
Also, Both drives are running the Atari Hard Disk driver, the Supra driver
was deleted from floppy which we didn't notice until we had formatted the
hard disk.

Also What about null modem between the two machines, I can make the
cable easily, but don't know what software can be used to send files
between, any ideas?

ONM07@DMSWWU1A.BITNET writes:
>Sorry, there is no such flag in the boot sector. It's only in a BPB.

MSDOS draws the line between 12-bit and 16-bit FATS at the point where a
12-bit FAT cannot work: 4096 clusters. I think. GEMDOS' floppy BIOS is
hard-coded to report 12-bit FATs, on the assumption that it won't be called
upon to deal with any 2.88MB floppies with one-sector clusters.

You should be asking, "IT DOESN'T CHECK THE NUMBER-OF-FATS FIELD IN THE
BOOT SECTOR??" That's a far more serious problem. You had better not try
writing to a PC-formatted disk that only has one FAT, as some do. The
number of FATs is in the boot sector but it's not passed to GEMDOS in the
BPB: GEMDOS is hard-coded for two FATs.

Hey! I am lazy, but not too lazy to switch off! I've been switching it on and
off like an illuminated ad sign, ever since I got the machine!
But I've heard such conflicting tales about the horrific things that can happen during
switch on/off, that I
thought I'd see what the network tech gurus thought. So far, the responses
have been reassuringly confusing :-)

Source record: 47514

i have owned an ST since 86. my general work habits are to leave it on for days at a time. currently i have a mega4 and megafile 60. i also have a 1040 and sh204. never had any problems due to this.

i have had to replace the floppy drives several times, however. once on the mega and 2-3 times on the 1040. and i probably bought 2 or 3 mono monitors (i do blank the screen when not using it with my own manual screen blanker). IMHO the floppy is the weakest (and cheapest quality, so it seems) component. the electronics seem solid (if u keep it cool).

i generally keep the room < 80 deg F and keep the venting unobstructed. the mega/megafile are made to be stacked which is what i do - megafile on top of mega, monitor on top of megafile.

i also use a CA power director for surge protection (helpful when the electric company decides to cut power, which happened during just about every non-trivial storm in syracuse - my TV fried, but the computer survived). this is the $130 model, not the cheap $15 power strips. it saved my ass more than once and was well worth the money.

i think heat is the big enemy, not bearing failure. i only had a bearing on a hd go out once. that was on a transportable pc (panasonic sr. partner circa 1985). maybe i checked it thru baggage one to many times :-).

NO! Fix the bugs now! Tell the developers now! It will take at least a year
before Joe User sees the ROMs as it is.

>2. Providing little PD patch programs so that developers can see if their
> programs will fall foul of the fixing.

Seems reasonable.

>3. One year on, fixing the bugs. Ignore those who whine.

I always do.

>I'm currently vaguely considering a TT to go with my two STs, or maybe a

No question, you can do that. Using a newer flavor of HINSTALL, it is
possible to install and remove the driver on the fly. You won't have
to remove the driver just for a copy session, though. Just take care that
the two drives use differenct ACSI target numbers.

Seems to be the time to introduce something like an 'extended BPB' as found
in newer MS-DOS versions (or was it OS/2?). Should be possible to do it in
a backward compatible way.

Source record: 47521

Here's some background to my problem...

I'm trying to write a picture viewer for TT low and TT medium resolutions using just xbios and line-a calls. (Forget GEM.. 1st I've not got any docs on GEM and 2nd WIMPs are for Wimps :-)).

Anyway.. I have two problems...
1) How do I access the 4096 colours with only a 9 bit value using the xbios call Setcolor()?

2) How do the colour numbers referred to in Setcolor() map to the colour numbers used int the line-a functions?

At the moment the images produced by my raytracer (rayshade v.4.0(Beta)) are recogniable, but are in some wierd and wonderful colours!

I just checked it ... it works fine. Does anyone have an idea how to code
such a 12/16 flag in the boot sector so it can be read by such a TSR?
Which field should be used for this?

Daniel

3041. digital samples question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-23 21:25:40 UTC
From: trux@beyond.caltech
Message-ID: <TRUX.91Jul23142540@beyond.caltech>
Source record: 47526

Hello ST community,
I wonder if anyone knows anything about how digitized sounds are played back on an Atari ST. I have a digitizer for my IBM which produces a file of size [4000 Bytes for each second of digitized sound]. I want to use these files with my ST. Each byte corresponds to one of 256 different voltage levels to be applied to an analog speaker. A large difference between two consecutive bytes produces a loud 'click' and a small difference produces a small click.

I tried playing a constant tone over the Atari's speaker and setting the volume (0..15) 4000 times per second, but this has 1/16th the resolution of my digitized sample and the replay quality is VERY poor.

I know that impressive digital replay is possible on the ST, any ideas how?

Thank you,
-trux

>1) How do I access the 4096 colours with only a 9 bit value using the xbios
> call Setcolor()?

9? I thought it was 12. Setcolor(0,0x777) [or is that Setcolor(0x777,0)] sets colour #0 to white, so I assume that, since the bits are ordered 3, 2, 1, 0 in significance, Setcolor(0,0xfff) would make colour #0 slightly brighter, while Setcolor(0,0xeee) would make colour #0 slightly less bright.

0x000, 0x888, 0x111, 0x999, 0x222, ...

NB: I don't have an STe or TT - this is superstition. When you look at it though, Atari didn't leave themselves much choice - we couldn't have the top bit as most significant, or else stuff written on ST's would be dark on STe's and stuff written on STe's would have a colour discontinuity. Why didn't they do what they did on the 8 bit? ie. 4 bits, LSB insignificant. Logic defies.

Warwick
ps.
pallet and palette are synonyms... Atari compromised :-)
Setcolur maybe in TOS 6.0 ?

3043. MiNT library patchlevel 10 now available

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-24 03:37:11 UTC
From: ersmith@ria.ccs.uwo.ca
Message-ID: <3843@julian.uwo.ca>
Source record: 47528
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I've uploaded the source code and binaries for the patchlevel 10 of
the MiNT library to atari.archive, in the mint directory. There are
a *lot* of changes from patchlevel 8; most are cosmetic (removing
various compiler warnings) but there are some significant bug fixes
as well.

Most notable of the fixed bugs was one in open(); the old version was
passing the "mode" argument unchanged to Fopen. This was a *very* bad
thing to do; in fact, only the lower 2 bits (O_RDWR, etc.) should
be passed. It doesn't matter (much) in the current version of MiNT,
but it could cause very severe problems in future versions of MiNT.
I would strongly suggest that you recompile all your MiNT programs
with the newer library (or at least with a fixed open()) so that
the transition to MiNT 0.9 won't be quite as painful :-(.

Other changes include drastic changes to the include files to handle
prototypes more easily, and to improve portability to other compilers.
I've also incorporated many of the changes to the "standard" gcc
library that Jwahar Bammi has been maintaining (thanks, bammi!).

HELP!

I've asked this before, but I lost the responses I got.

I would like to know if anybody has successfully upgraded the Atari SH204 to another size. I know that using other software like Supra's I could install any drive I'd like, but what if I were to use Atari's HDX 3.01?

What are the drives that Atari uses in the Megafile 30's or 60's? I would like model #'s etc.

Thanks in advance.

Dom

The trick is not to use only one voice but to use all three voices. You have to switch to the highest frequency possible and then turn off all voices. All you have to now is put the right value into the level control registers. You have to think about the fact that the volume increases in an exponential way, so by combining the right values it is possible to have a nearly linear DA converter.

(1) You wouldn't even HAVE all these problems, if you would use the standard
VDI interface.
(2) You actually have 12 bits, 4 for R, G and B. The highest bit maps to
the least significant bit.

There's a huge conceptional mistake ! Keep off Line-A !

Why don't you take a look at some VDI-manual to see what you can gain from it ?

Is there some MS-DOS machine available with ED-drives ? If so, how
does the disks look like ? Do they have 12/16-bit FATs, a clustersize of
1/2 k, etc. etc. ?
(I don't think such a beast is available, at least not as a standard drive)

So, let's assume we have connected an ED-drive through SCSI. We could
treat the ED-disks just like removable disks, similar to the SQ555-cartridges.
Now we have 16bit-fats automatically... So where's the problem ?

Greetings,
RIPLEY

I would like to buy my friend's PC-DITTO II from him
but... He has no PALS for it!!

He sent them away for the upgrade they offered but
they went belly up before he got the replacements.

Is there anyway to get these devices?
You can't copy them , cause the security fuse's are blown.

Has someone got a spare set?
Has someone got the PAL equations?
Has someone got a person to contact , formerly of PC-DITTO?

Help would be greatly appreciated.

I have been told that the graphics routines built into the operating system are not efficient. I am tinkering around with 3d graphics and would really like to get my hands on some (FAST) graphics routines. Specifically, a line drawing routine, a filled polygon routine, and a filled ellipse. If you have some of these, I WOULD REALLY like to have them. I am sure others will too.

Thanks in advance!

I have a friend who is trying to get his 1040 working properly...
I told him its a power thing since he has so many things hooked up to it..
Its in an IBM case
4meg of memory (Original memory removed)
T-16 accelerator
IBM keyboard adapter using an IBM keyboard.
DreamParks 1.44meg upgrade
And ICD's dual tos rom hookup..
(He is using an ICD hard drive kit inside the PC case as well as two 1.44 meg floppies.)

When he adds the Dual Tos rom thingy it wont work properly.. It works right if he disconnects the hard drive.. Or if he removes his hard drive and uses the Dual Tos's he can get it to work but it wont switch for him..
He's having all sorts of problems with it..
My understanding is that he is using a 150 watt power supply..
Any clues or tips?

(I was thinking he is overdriving something somewhere and possibly plugging another power tap might help out some?? But where the tap would go is another question...)

> (terminator.edu?)

If you're willing to pay out a small amount of money for a commercial product, I'd recommend Fontkit Plus by Jeremy Hughes. Extensive editing facilities, and extra programs to convert to and from a wide variety of formats. It's well supported - there have been a number of updates, at reasonable prices.

It's available for 19.95 pounds plus postage from The ST Club, 49 Stoney Street, Nottingham, UK. They also have a big PD catalogue which includes a good number of GDOS and other font collections

(I'm an ST Club member, and use Fontkit Plus occasionally, but have no monetary interest in the product.)

3059. supra clock

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-25 12:19:12 UTC
From: Roger.Sheppard@actrix.gen.nz
Message-ID: <1991Jul25.121912.18250@actrix.gen.nz>
Source record: 47396

Can some one help me with the Supra Clock Problem,
this is the problem with the Clock Chip, Part No.
RCA CDP6818 or Motorola MC146818 draging down the battery.

I read some where that Supra was replacing faulty Clock chips.

But the real problem is that this clock chip uses to
much power 50ua max, from the RCA data book.

I did ring Supra to find out, but I was told that I
would have to send my Host Adapter back for them to replace
the Clock IC, with a Dallas one.

This was not just a plug in job, traces have to be cut, etc.
I asked them if they could give me the details,
so I could do it myself, I told them that I was a competent
Computer Engineer, no way and could not even give me the
Dallas clock chip part No.

So is there some one that can give me the Part No.
of the Dallas Clock Chip, and also if Possible some of
the changes that where made to use this device.

If I get the Dallas Part No. I can possibly work out the modifications
for myself, but will post the information here for otheres to carry out.

From what I can see in the Dallas data book, they make 99.9%
compatible MC146818 that have a 10 year life with the
built in battery, Part No. DS1287 and one with a external battery
Part No. DS1285/Q with a current drain of 100 time less than
the MC146818.

Note: I also found out that there software version 4.01, (latest)
does not support BGM partions.

Thanks, Roger..

>I have heard ENOUGH! I don't see why everyone has problems with LZH and
>LHarc.. All you need to do is use UNLZH 1.72 and all your files will be
>unlzh'd easily and painlessly! It uses a nice GEM interface and I have
>had *no* problems with it.

I have to agree with this, and I've said it before myself. I use unlzh
1.72 by John Harris to extract on the ST, Lharc 1.20 (1.30 as of last
night) by Roger Burrows to LHarchive on the ST, and Lharc 0.03 (Beta)
by Y. Tagawa to extract and Lharchive on Unix machines.

I upload and download tons of stuff and I've never had a problem. Not
once. I believe that early incompatibility problems have been solved.

A few interesting things I've found about archivers in general:

o If you Arc an already-compressed file, Arc will fiddle around
for a while and then say "Storing", which is most likely the
correct thing to do. HOWEVER, it seems that if Arc changes its
mind like this (from crunching to storing), the Arc file is
* strangely large *. My recent DigiStuff posting is an example:
I Arc'ed the self-extracting LZH file alled DIGISTUF.TOS and
came up with an Arc file of about 250K. Then I forced
"storing" by using "arc as ..." and the archive came out to
be 215K. Perhaps Arc is storing CRC information in the first
case but not in the latter? Still, it seems strange.
BTW, this is with Arc 6.02ST.

o Of all the LHArchivers, Roger Burrows' seems to make the
smallest files. The Unix LHA 0.03 (Beta) makes files that
are a tiny bit bigger (no surprise I guess), and * strangely *
the otherwise excellent Lharc 113 from Thomas Quester makes
.LZH files that are several K larger than their Burrows LHA
counterparts, at least in the several cases I've tried. All
three lharc programs can uncompress files made with each
other, though, even though the compression factors are
different.

o The new Zoo 2.1ST at least sometimes creates smaller files
than even Lharc. Here are the results of a recent test I ran:

```
mrw------- 1 u 251231 update.zoo (hi)
mrw------- 1 u 283792 update.lzh
mrw------- 1 u 395288 update.zoo (normal)
mrw------- 1 u 418149 update.arc
```

```
mrw------- 1 u 1125376 update.tar
```

The tar file consisted of mostly C source files and DRI .o files. With "high compression" Zoo 2.1 achieved 78% compression. Burrows' Lharc 130 was close behind, but the other schemes seem much less effective. With "normal compression," however, Zoo gave its typically sad performance. Given my personal experience with Zoo, I was actually suprised to see it do better than Arc in this mode.

Granted, this is only one example. But it does show that at least for some kinds of data, Zoo 2.1 gets compression factors favorable to those previously achieved only by the "dreaded" Lharc.

Just some food for thought...

I once tried to arc an uucoded arc file with unix 5.12 arc version
after about 1/2 an hour I got the message 'Disk full' or something
it turned out that the arc program used up about 100Mb diskspace
(OK it was a large file 1 a 2 Mb, but not that large)

I think it is the 'crunching' algorithme thats breaks down under certain
conditions like compressing compressed data. Therefore you could consider it
to be a bug of the arc program not recognizing this.

Am I wright? (any comment of programmers of various compressors)

Open letter to Ralph,

I started with the file "crabs" that I took from the binaries news group.
I tried UUD on my MIPS machine. I got segmentation fault, just as you did.
I tried uudecode on my MIPS machine.
A file called crabexe.lzh was created.
I then used UUE on MIPS to encode it, and got the file crabexe.uue.
Then I did "diff crabs crabexe.uue > t.di". (so far I have four files).

-rw-r----- 1 ljdickey 2174 Jul 25 18:09 t.di
-rw-r----- 1 ljdickey 10330 Jul 25 18:09 crabexe.uue
-rw-r--r-- 1 ljdickey 7304 Jul 25 18:08 crabexe.lzh
-rw-r----- 1 ljdickey 12333 Jul 25 18:08 crabs

Here is the important stuff from t.di :

1,43d0
...
< Message-ID: <binaries.15.53@twitterpater.eng.sun.com>
< Date: 4 Jul 91 17:32:04 GMT
```

```
[...]
< o /
< >--------X--snip snip snip-------
< O \
210c167
< ..8>OG83<SX LGU[._T "Jt
---
> ..8>OG83<SX LGU[._T"Jt
213,214d169
<
<
```

In my explorations, I found that if I now used the revised file,
(the one with the <T">), that UUD and uudecode would both handle
it and both gave the same results.

Of course, the ".lzh" _appears_ to be corrupted, but I did not
move the file to the ST and try to run it. It might be OK.

Comments about uudecode:
I know that the first char of a line (usually the M) tell how many chars
the decoder should find on the line. The "." (first char) seems to be
saying, pick up <..8>OG83<SX LGU[._T ">, then UUD looks at the next char
and says OOPS, the J is wrong, and should give a "sequence error".
On the other hand, "uudecode" ignores superflous characters. (It
ignored all of the trailing characters "z", "y", and so on, from the
top of the file. If your "uudecode" does not ignore superflous chars,
it is not "standard".

I hope this helps.

Where do I find a good desription on how to program XBRA, I have scanned my dev docs but couldn't see anything. So does anyone know where to find XBRA in the docs or where else to look.

Thanks,

No, no! I was speaking of an extended BIOS parameter block (BPB), not of
changing the boot sector format.

>I am considering upgrading to an Atari TT. As I understand it TT's
>only come in two models: the TT/2 and the TT/8. Is the ST RAM *only*
>on the mother board, or is half of it on the extra TT RAM card?

A. Pratt from Atari posted info about TT RAM a while back. Here in the U.S.
one can purchase TT/2, TT/4 or TT/8. The TT/2 is ST RAM 2M on the Mother
Board. To upgrade or purchase TT/4 you will get 2M more of ST RAM on
a ST RAM daughter board. To upgrade or purchase TT/8 you will get another
daughter board with TT RAM - another 4M of RAM (these are SIMMs -
no SIMMs for ST RAM).
>
>Also what kind of RAM is in the two types of RAM for the TT: SIMMs,
>SIPs, chips, or some mixture of the above? I would prefer getting a
>TT/2 and upgrading the ST RAM to 4 Mb in the case that SIMMs are
>involved. I would probably later on, sometime next year when the
>European plant for 16 Mb chips starts operation, get the faster TT RAM
>when prices would fall.
>--
You can expand ST RAM to get a total of 10M. If you replace the 1M SIMMs
from the TT RAM daughter board with 4M SIMMs you will get 16M of TT (fast)
RAM. That means total memory could be 10M + 16M = 26M.

>Got a Mega 4 ST. Wishing it was a Mega STe! :-| Do I *really* want a TT? ;~#

You may not want a TT - STe is much cheaper and you can update memory with SIMMs.
I have a TT and a ST. Many programs run on both, but of course, most games from
the ST will probably not run on the TT. I believe that all of the Double Click
Software that has been posted in the binaries is ST and TT compatible.

CUL,
Chuck

3071. Atari and Hard Disk Problems

>Thanks in advance,
>AYLESWORTH,DAVID VINCENT

I seem to be in the same boat, even with a different configuration.
The problems appear similar enough that there may be a common solution.

I have (1040 ST - 1Meg tos 1.0, 1040STE 2.5 Meg tos 1.4) and
a Supra Hard Drive 20 Meg (Version 4.05 and 3.2 formatters).

The short part of the story: it works consistently with the
1040 and dosn't with the STE. I've reformatted the disk with the
new supra format software, and the software reports 90% of
the sectors as bad. When I format the disk with the 1040
using the same version of the software only 3 sectors are
marked as bad.

At this point I'm not even trying to boot from the hard disk, I would
be satisfied (for now) with being able to write files to the disk,
and being able to read them back. Executibles won't work and
picture files are corrupted and displaying the file locks the
machine.

Any ideas, anyone? (I'm seriously toying with the idea of
sending the 1040STE back to the dealer for a refund.

Has anyone set up a STE tos 1.4 to work with a Hard Disk, espec
a Supra Hard Disk?

So I misunderstood you. But I still think we don't need an extended BPB
for the purposes mentioned. Alternate file system will probably be handled
by MetaDOS in future, so BIOS is all out of the way.

DC No-Stic will prevent hard disk stiction from happening. Stiction
was such a problem with Seagate drives that they put in circuitry to
move the hard disk heads after a length of disk inactivity. DC
No-Stic emulates this logic.
100% assembly. ST, STe and TT compatible. Work with all hard disks.

I think this might be your problem! The STe line requires TOS1.6
or higer to support it. If you are using TOS1.4, you have not only downgraded
but are doomed (I think) to have severe problems. What happened to your
original TOS? It should have come with >=1.6.....

If you're capable of reading german, try the 'Profibuch' (Sybex). It's a very
good, detailed book about hardware and all BIOS, XBIOS, GEMDOS, AES, etcetera
calls. The newest version (to be released soon) will be 1300 pages (!!) thick,
also covering the STe and TT. More info? Reply!

Tos 1.4 does not work with a STE, from what you have stated here,
you have the Famous STE DMA Bug, get the DMA Chip replaced or
get a later STE.

Note: Later STE's have brass plugs underneath, where the mounting screws
for the main PCB, screw into the base, just tip over the machine and look,
for some small brass inserts.

Just thought I'd drop a note to the net letting all of our international friends know that Double Click Software will be attending, displaying and selling our wares at this year's Atari Meese show in Duesseldorf.

We will be showing something of particular interest to owners of AT Speed or PC Speed. Can't say more, you have to wait. :-)

We will also be showing (but not selling) our new game authoring package. Wow, it is hot!

Plus, our DC Utilities, DC Desktop, DC Shower and (tadum!) Data Diet - the _only_ realtime compression program for the Atari computer. Not to mention our DC Port serial expansion cartridge, too.

We really look forward to meeting our net friends face to face (and sharing a few rounds with them too!).

Hello.

Perhaps this is interesting news for you: There is a new version
of lharc (lharc 2.0) which has a new compression method. It packs
better than zip. I could send Thomas Quester's version to comp.binaries,
but I better ask him first...
Anyway, it has already been distributed through the Maus-net here in
Germany...

Greetings,
RIPLEY

What about coding it in the media byte, which isn't used on the Atari ST?
(Don't tell me anything 'bout DOS compatibility, such disk won't be readable
on a DOS machine anyway...)

How about getting a discussion about Turbo C 2.0 bugs for the ST?

I have 1 that I have found, very annoying. Maybe we could share?

Or compilers in general. That would be fun, and useful at the same time.
Then we can knock on compiler writers, instead of Atari Corp! :)

And everyone knows MY opinions about Atari...right? :)

Look for the program fix_gdos.prg at atari.archive (I think it's in /atari/utilities/tosfixes, but don't hold me to it). It's fully XBRA-conformant and includes assembly source code. The comments are in German, but you should be able to figure it out.

For the record, I am not advocating that you lift the XBRA code from this program and use it verbatim (at least not without the express permission of the author), merely that you study the code (after all, why else would the author have provided it?) and learn how to implement XBRA for yourself. The more people understand standards like XBRA, ARGV, and their ilk, the more people will use them, and the better our life will be (I could say the same of the cookie jar, but that's another story).

3088. Grandson of the 40-folder bug

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-28 18:46:17 UTC
From: Scott.Bigham@bbs.oit.unc.edu
Message-ID: <4813@beguine.UUCP>
Source record: 47425

I think I'm being bitten by a variant of the 40-folder bug and I seek advice.

Background: I'm running TeX on a 1-meg 1040ST, TOS 1.0 circa 11/20/85, FOLDR100.PRG (about as much as I can have and still run TeX). Everything works as advertised until about the eighth or ninth invocation of TeX or DVIATARI, at which point the system seems to become suddenly unable to open any file anywhere, a symptom I've always associated with the 40-folder bug. If I reset the computer, everything is fine again.

Now, DVIATARI touches several folders in its quest for fonts, but it's always the same folders, so apparently the system is using a new slot every time it touches a folder. Obviously this is an unclever thing to do, but if there were an easy way to do things cleverly, this whole problem would have been fixed by now.

So, short of hitting RESET every twenty minutes, is there any way to clear out the folder slots or correct GEMDOS's view of reality? I'm almost desperate enough to try catching the GEMDOS OPEN and CLOSE calls and building some intelligence into them, but I'm a little edgy about that.

[If this isn't the 40-folder bug at all, or if I'm missing something obvious, please tell me gently :)]

I get a similar problem with the 1st2pw prgram that converts 1stword to
postscript. After doing a certain number of files, it freezes, and the
only thing that works is to restart the program - I don't have to reboot.
Is this the same phenomenon?

Sorry if it bugs you, but two comments: One I don't have access to any
other ST newsgroups. Hence the fact that I have ONCE or TWICE posted
messages re: games. And, second, So wat if we do. Maybe it's not totally
"legal" but it's not like it costs you money. Sure posts add up, but it
costs the same here or there.

Well why not save yourself a lot of Problems and Go get TOS 1.4, this
has a lot of improvements to the Folder Bug, and lets you sleep better
if you ask Atari about any Problems the First thing they say go fit
TOS 1.4 then you can complain..

3093. Default Font specs....

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-29 04:42:00 UTC
From: cmedley@wam.umd.edu
Message-ID: <1991Jul29.044200.5384@wam.umd.edu>
Source record: 47432

I know this is probably "illegal" but....

I have a program that fixes its own resource file(s) up. I'm only using one .RSC file for it, so in order to make it work in ST color and mono, I have to "scale" the character coordinates by the size of the default character set (font) used in that resolution.

In mono, this is 8x16, in color it is 8x8, and I understand that the TT has others(?), so I'm trying to find a consistent way to get the standard width and height of the default system font.

I've tried using vqt_attributes, but this fails under MultiDesk, since that program has everything set up for a 6x6 font. vqt_fontinfo seems to be a potential winner, but it sounds like it won't be consistent on a system with GDOS installed (I don't know for sure).

I've looked through my ST developer docs, and looked at the information on VDI font formats, and realized I could use the Line-A, look into the FONT_RING, and find the default system font and get the specs on the font that way, but I would just like to get an idea of whether it is worth it to go that route, since it seems like a lot of code to get the job done.

(incidentally, according to Abacus' GEM Programmer's Reference, they claim the font sizes returned from a v_opnvwk are inaccurate, and only return the monochrome 8x16 font's specs.... I wanted to know if this is true even now, with the newer machines....)

Take a look at rsrc_obfix(). This function does all what you need.

>Where do I find a good desription on how to program XBRA, I have scanned my
>dev docs but couldn't see anything. So does anyone know where to find XBRA in
>the docs or where else to look.

Just a quick example in 68000 code: Suppose we want to re-direct the
hdv_rw vector to check for a drive of our own or whatever. The following
code assumes we're in SOOOUPER user mode and that the vector handler
and assorted stuff stay resident.

```
...
move.l $476.w,o_rw ; get old vector and store it
move.l #new_rw,$476.w ; install own vector handler
... (make code resident, terminate, try to fool your users or whatever
you like)

dc.b "XBRA" ; XBRA magic
dc.b "F0AD" ; special magic designating our program
o_rw:
dc.l 0 ; longword to store the old vector
new_rw:
cmp.w $E(a7),ourdrive ; do we want to handle this drive?
beq.s ownstuff ; yes, so don't hesitate
tooldhandler:
move.l o_rw(pc),-(sp) ; get old adrress
rts ; and jump to it
ownstuff:
...
```

After several programs linked into a vector following this protocol,
a linked chain is built up. Knowing this, it should be easy for
you to program a routine that follows a vector chain.

The special magic your program uses to identify itself in the
chain should be unique. To make sure your ID is unique, you should
have Julian "Master of the XBRA list" Reschke register it.

I just don't think we need 16 bit FATs on standard disks. Different story
with ED disks, but we'll need special drivers for them anyway.

If the only newsgroup you received was rec.humor.funny, would you
use it to post questions about computer games?

Not having access to comp.sys.atari.st is not a valid excuse; that
shortcoming can be fixed easily enough. See your local system
administrator. Don't abuse Usenet because of a flaw in your local system.

The charter of comp.sys.atari.st.tech is clear. Games and for sale
postings are inappropriate. This newsgroup was created specifically to
segregate technical postings from nontechnical chatter. Keep it that way.

>postings are inappropriate. This newsgroup was created specifically to
>segregate technical postings from nontechnical chatter. Keep it that way.

For everyone's information, here's the actual charter which was approved
last July (wow, it's been a year!) when I ran the vote:

Article 27996 of comp.sys.atari.st:
Newsgroups: news.announce.newgroups,comp.sys.atari.st
Subject: CALL FOR DISCUSSION: comp.sys.atari.st.tech
Message-ID: <1990Apr13.225146.7988@wam.umd.edu>
Date: 22 Apr 90 22:51:46 GMT
Sender: lear@turbo.bio.net
Reply-To: dmb@wam.umd.edu (David M. Baggett)
Approved: lear@turbo.bio.net

[...]

Charter
------

comp.sys.atari.st.tech will be devoted to technical discussion
regarding Atari ST software and hardware. Examples of topics to
be discussed in this newsgroup include:

"What are the pinouts for the ___ port on the ST?"

"Has anyone managed to hook up a ___ successfully?"
(Assuming this is a nontrivial task)

"Which system vector controls ____?"

"What is the official, Atari-sanctioned method of doing ___?"

"What are the specs for ___ file format?"

"How does ___ manage to get 20 million colors on the screen?"

"What is the best way to do fine scrolling?"

Examples of topics NOT to be discussed in this newsgroup include:

"How do you get past the dragon in ___ game?"

"For sale: ___"

"New product announcement: ___"

"My ST is better than your ___ because"

"My ___ is better than your ST because..."

"Atari's financial situation is ___"

Generally speaking, I think there have been very few "infractions" in the first year, and fortunately not a whole lot of net.policing either. In fact, compared to the vote itself (anyone remember?) life's been cheery here!

Let's keep up the good work...

Dave Baggett

i have always used
graf_handle(&wchar, &hchar, ..., ...);
for this purpose, and fixed up the resource using whatever it gives
back. i seem to remember that if you were doing this, the root object
(but not all objects) had to be aligned on the character boundary or
some such...

a) you should really move up to tos 1.4

b) use showdvi instead of dviatari: a far superior/faster program, and it packs all its fonts into a library, so it does'nt have to go searching all over the filesystem, open that many files, much easier to maintain etc etc.. it should be on A.A

>CAN THIS BE DONE!!! How???

Okay, let's see...

512 is easy - You just restrict the number per line.

Then, to get more than the actual ST pallette, you have to use flicker-methods (or buy an STe/TT!).

Quantum paint I recall uses flicker to get 4096 colour pallletttes, then uses the Spectrum-style horizontal-scan-synchronisation to allow that many colours on the screen at once.

By extending the methods, you can use up 1 megabyte of memory and get 16 million colours on the screen.

Trivia :-),
Warwick.

3106. TT RAM

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-30 07:19:06 UTC
From: univwa@sbuvax.rz.uni-sb.de
Message-ID: <12167@sbsvax.cs.uni-sb.de>
Source record: 47341
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech,dnet.atari

Hi there,

I have some questions concerning memory upgrade in TT030:

I have a TT030/6/48MB, achieved in Germany in 11/90:

- How can I upgrade the ST RAM? (now: 2MB)
What kind of RAM Chips do I need?
Where are they sitting? Socketed on motherboard?

- How I can I manage to upgrade TT RAM? (now: 4MB)
(same questions as before)

I know that I may need a so called daughterboard, is this beast already
built in with my 4MB TT RAM?
Where can I buy such a thinW?

Thank you for your help.

greetings Bernhard

Unless I'm mistaken, though, showdvi only supports mono. I got dviatari specifically because it seemed to be the only one that would work with my color monitor.

Yes, absolutely; off hand, Toad, Joppa and Best Electronics sell TOS 1.4. If I get enough requests, I can post my tips file, since the docs for insertion are not as clear as the ones I got with TOS 1.0 for my previous 520. Of course, there was only one motherboard to deal with then!

Ah, but it might be...
Why sacrifice data compatibility if it is possible to retain it. The first
two entries of the FAT itself can indicate what size entries are in the FAT.

>I just don't think we need 16 bit FATs on standard disks. Different story
>with ED disks, but we'll need special drivers for them anyway.

16 bit floppy FATs are a rather unusual configuration but not entirely unlikely.
They are more human-readable and take a little less CPU time (not that it
matters all that much in most cases). Depending on controller / drive setup
the standard BIOS floppy driver will handle ED disks as well as any other if
the sectors per cluster is set high enough.

BTW: I heard that there was a PC driver out that puts ED density on HD disks
using HD drives. Comments anyone? I would guess this is more reliable than
punching holes in DD disk jackets to pretend they are HD.

Source record: 47349

Hello, you seem to have stuck to a nonsensical problem. There are actually no differences between using a SCSI interface or not as far as ED disks are concerned. If you use a SCSI, you will have to make sure that your SCSI driver supports the ED drive. If the ED drive is clever enough and can format the floppy in the standard way (some parameters and then the format command), it will be straightforward. In this case the software problems are contained in the firmware of the SCSI drive. Note that while hard disks are pre-formatted and have a sector that registers the drive's specification such as bad sectors, formatting data and so on, the ED floppies and normal floppies don't have those. That's why you have to give some parameters to the SCSI firmware. On the other hand, your no-SCSI ED driver will be doing what your SCSI firmware will be doing. Therefore, if you are not good at writing device drivers, you could disassemble the firmware and translate part of it into 68K. This is hardly recommendable as writing a device driver for an ED drive is so easy.

All these futile debates on BiosFat routines (I have never thought of bios routines handling FAT's) derive from a lazy attitude of not being willing to writing the right device driver for the ED drives. As a matter of fact, writing a device driver on atari is very simple: just writing a small subroutine that reads/writes the logical sector N on the device and return a reply to a media change query. atari st cannot distinguish between a RAM disk and an ED disk basically.

Source record: 47352

Hi! I just starting experiencing a weird problem with my 1040ST. It has been upgraded to 4 Meg with an JRI board, installed by a dealer in Philadelphia, and has been working great until a few days ago. I noticed that after having the machine on for a while (about 20 minutes) it hung up. If I reset it or power it down and then up immediately nothing happens, but if I wait long enough (presumably until it is cold) it comes up OK. I am not a hardware type of guy, but my guess is that it is some circuit which opens up when the machine is hot. I remember the dealer told me that the board couldn't fit with the rf shield so he took it out. Any comments/suggestions/help will be greatly appreciated.

[In article <1991Jul30.161057.21064@parc.xerox.com>,
goldthor@parc.xerox.com (Stephen Michael Goldthorpe) writes ...]

> Are there any public domain/FREEWARE resource compilers available. I'm
> just starting to have a go with GEM and need some way of creating
> resource files (either interactively or compiled).

Jim Charlton's resource editor was published in comp.binaries.atari.st
and comp.sources.atari.st. It can be fetched from
archive-server@twitterpater.eng.sun.com by sending mail with the following
commands:

send sources/volume3/mkrsc part01 part02 part03
send binaries/volume13/mkrsc part01 part02

The resource editor creates .RSC files and .H files for a C compiler, but
not .C files. To get .C files from .RSC, use Bob Silliker's RSCTOC program,
also available from twitterpater. (You don't need .C files unless you intend
to bind the resource directly into the executable program.)

I found that Jim's resource editor works just fine, but it's fairly basic
-- lacks the ability to edit icons and images, for example. After you get
used to GEM, you may wish to buy a commercial resource editor such as
WERCS.

3116. Problem making up a monitor lead....

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-31 11:11:49 UTC
From: simonp@sun.pcl.ac.uk
Message-ID: <1991Jul31.111149.9336@sun.pcl.ac.uk>
Source record: 47353

I'm currently trying to make a lead to connect my ST to a Hitachi CPT 1444.
Unfortunately it doesn't seem to want to work!

Everything works except that the picture breaks up when there is a large
amount of white on screen, to the extent that a totally white screen results
in a loss of vertical lock/hold.
I put this down to having used the composite video as the sync input!
(Vertical Sync from the ST doesn't work at all)
The Hitachi documentation refers to "Sync (-ve)" on the pin diagram whereas
the ST documentation offers "Vertical Sync" & "Composite Video" pins.

Can anyone tell me the correct way to do it? [please!!]

Any help is greatly appreciated, Simon.

Tos 1.4 is like gold dust in the UK, more so over finding out that there are two different ways that it can be bought, (2 chip set or 6 chip set). Having checked and discovered that I was a two chip set person, I starting ringing round the mail order companies in the UK. Only Ladbrokes (sp) based in Preston had the two chip set and they were out of stock and did not know when it was coming in again. Other companies had the 6 chip set for sale. I asked around my mates and discovered it is possible to install the 6 chip set in a two set machine if I sit down and solder in 4 sockets and make (or break) a link and the motherboard.
Having desoldered and sockect the shifter chip this should be no problem but it took me six weeks or so to believe that the ST was still working after I have done that small operation. (And I was thinking of installing a blitter chip)
So I wouldn't mind looking at any tips of how to install it as it appears that my machine is completely different to every one else (Why my shifter was not sockected I do not know every thing else is, the MMU, TOS 1.2, the GLUE chip)

Yours

Dave J

I would wait till the machine heated up, had the problem, then take
a continuity tester and check the solder points to the motherboard.

OR

You can take a can of FREON and BLOW each contact and see how the machine
responds upon BOOT UP.

16 bit FATs have one serious advantage: They make debugging much easier.
I hate this kind of doublethink you need to correct a corrupted 12 bit FAT.

Just a minor correction to your post Steve... MKRSC can create .C ouput
files. They are also somewhat easier to use than than those created
by some of the other utilities. Perhaps you still have one of the beta
test versions of MKRSC which did not have the .C output option included.
There was only one official version of MKRSC released (vs 1.0) but it did
include the .C output option.

Well, to start you need, 1) a Host adapter, 2) Controller Board,
3) 50W Plus power supply, for starters..
4) 45Meg or more hard drive...anything smaller
your wasting your money in my opinion.
Recommend a Seagate, or if you get beyond
80, check out RODIME, QUANTUM drives.
5) Some kind of housing, ribbon cables and
ASCSI cable connector.

I think most people here would agree with me that ICD is the Hard Drive king!
They make very good equipment..I am impressed anyway. Very fast TOO.

Explaining how to hook something like this up over news is probably a bad
thing to do, save your frustration and either:

1) Be daring and follow the directions with an HD kit...

2) Seek out your local Atari Dealer (Don't forget your weed hopper).

3) Seek out your local Atari User Group, (more of those around by far)
and get some help.

--And good luck!

--Greg

Always an Atari owner, but always critical of Atari.

I have heard that it already has been released. (ComputerShop Utrecht aught to have it) It costs 109 Dutch Guilders (+- US $ 55) and a diskette also comes with it.

The version of showdvi I have supports color too. I have the latest
one to be posted to comp.binaries.atari.st; I assume that the one on
atari.archive is at least as recent as this.

I use showdvi on a color monitor, with very satisfactory results. I
believe it was only the very early versions of showdvi that were mono only.

3126. Why not a universal extractor?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-07-31 21:14:24 UTC
From: tdrga@ccwf.cc.utexas.edu
Message-ID: <53343@ut-emx.uucp>
Source record: 47362

Since there is a great controversy about which archive program is best, fastest, most compatible, etc. --

Why hasn't someone written a 'universal extractor (tm)' which would extract ARC, Lzh, ZOO, etc. files automagically?

It seems simple as far as the main structure of the program goes:

- Read file header, dettermine file compression scheme

- Jump to {subroutine,module} which extracts files from archive

I realize that there are programs like ArcShell, etc. which provide a graphical interface for the .TTP's, but if the sources for the compression schemes are available, then it shouldn't be too hard to put them all into one program - right?

Oh well, just a thought I had...

I dunno about destroying the ozone layer...

But Freon is used in tracing cold-solder joints. When the machine
gets hot, and dies, spray Freon is an _small_ area, usually just over
one intergrated circut chip, and if it works, wala! you resolder
that chip. Its a major freezing spray, nothing to play with. If I
remember, itll freeze down to about -100f. I gave my friend a nasty
burn mark, by spraying him with it...

(btw: why is it called a cold-solder joint when it fails when it
gets _hot_? :-) (just a stupid question, I know the answer...)

Well its not Automatic, and I find very Buggy,
they do have another called DCSHOW + or some thing like that
it could be Automatic, its only a extracter.

But with all these New archivers Zoo 2.1 and LZH 2.0, they all need a
rewrite..

I had a look at showdvi, it seemed slick however it wasn't apparent to me from the docs how to create a font library from a bunch of fonts. If anyone has created such a font library already, I think it would be a really useful service to upload it to atari.archive. (The fonts that I was able to find there were incomplete)

What do others think?

Why not finish it Howard? Roger Shepard claims DCXtract has some bugs. I've not tested extensively, but it wasn't as good as my regular archiving program when dealing with a screwy header on a non STE compatible DCSea file (I mean, I had to hack off most of the extraction program - voila very funky header 8-). Besides, you have to first pick which kind of archive you want to deal with, before you try to unarchive it. This is not what was asked for in the original posting. Sounds cool to me...

Hi.

What I'm searching for is a program like stdcat, that is capable of reading the contents of all kinds of archives. If I save net-stuff into archives like NEWS2412.ARC, it isn't useful to store the archive's name into the disk-db w/o storing what's inside. There are a few programs that store arc or zoo or something like that, but that isn't enough. I guess the easiest way to deal with that is to have an universal interface for the archivers and just call them to get the contents. For the purpose of disk-databases, it would be ideal to treat all archives like folders...

Greetings,
RIPLEY

I've always used the Atari RCS 1.4. It's not really PD but in Germany you can buy it for ~$8. WERCS I don't know, but I prefer it, inspite of some shortcomings, over Atari's RCS 2.0 (which is packaged with some commercial products).

And it's by Tim Oren...

Cheers, Jan

The next planned release of DC Xtract Plus has an auto detect mode for
auto selection of an archive type (on extract and creation).

DCX+ also handles imbedded archives (in self-extracting programs - PC too) in
its current release (I know, I've demonstrated it dozens of times at shows).

Additionally, DCX+ next release has other nice options (including auto select
to select files in the archive when you 'open' it).

Remember, this is _one_ program in the entire DC Utilities package.

You're right: the earlier versions were mono-only, but the *latest*
version posted to comp.binaries.atari.st (1.00T, I believe) supports
colour as well, even using the same set of pk fonts.
>
>

The documentation that I got with showdvi states that it is a
binary-only PD distribution. You might try contacting the authors,
but it seems that they don't want to distribute source, although they
might just do it for a fee.

3140. Bitmapping techniques

Newsgroup: comp.sys.atari.st.tech
Date: 1991-08-02 18:16:03 UTC
From: bittrolff@evans.enet.dec.com
Message-ID: <3696@shodha.enet.dec.com>
Source record: 47376

Greetings,

What techniques are available for bitmapping. Specifically, I would like to place pieces, or icons, on a static map on the screen, just like any one of a hundred games such as empire. What is the best way to design and move these icons? I will be working in MWC, and using GEM.

I suspect that this is a fairly easy thing to do, I just haven't played with it yet.

~^~^~^

3141. Program relocation information

Newsgroup: comp.sys.atari.st.tech

>Is Freon the stuff that is detroying the ozon layer of the Earth?
>By the way, how can thes help searching for problems in the motherboard?

Well, I never said the advice I gave was environmentally sound! But,
for your question about the freon. It cools contacts on contact.
If they aren't sound, soldering contacts, they will usually crash the
machine with great changes in tempreture induced by the evaporating
freon.

Now I have heard everything, environmentally sound computer repair tech
iques.

Ok, don't use freon....use isobutane...and blow yourself up! :)

<**********BOOOM**********>

It does work, trust me. Spot cooling circuits is a great way to tell
the pros from the amatuers...(I DEFINEATELY am an amateur when it comes to
destroying...errrr, soldering circuits....)

--Greg

PS: Atari sucks. We want UNIX, we want MOTIF, we want DEMAND a real OS.

AND I DON'T MEAN MULTI BLAH (GEM) either.

I've come across a problem with a program I am writing that steals the TRAP vectors on the TT.

It seems that it works fine on STs, STes, Mega STs, and Mega STe's, but not on the TT, and I've been told that this is because of a difference in how the TT is handling the TRAP exception.

The answer to this is supposed to lie in knowing how to react to the contents of a location in memory ($59e), which is supposed to tell me the processor configuration (or something like that) as I understand it.

Can someone out there explain exactly what the difference(s) are, and how Atari wants us hackers to handle these scenarios? I'd love to have my program work on the TT...

Hmm, and everytime there is a new version of one packer, the program has to
be rewritten. Look back in time, two months ago nobody had thought of
STZip, Zoo 2.1 or LHA 2.00.
I found a small programm that makes use of the "install application" feature
of the desktop. You can install it as standard application for all
arhcives, it shows the contents of this archive (except zoo 2.1, the
author doesn't know the header structure).
At last, you've got a possibiltiy to select the files to be extracted from
the archive. At last, it calls the corresponding archive in order to
extract that file.
Anyone interested?

3145. Stupid ICD hard drive question

Newsgroup: comp.sys.atari.st.tech
Date: 1991-08-03 23:07:58 UTC
From: plucky@ais.org
Message-ID: <1D9DF0&@irie.ais.org>
Source record: 47385

SHORT VERSION: Can you split a partition into 2 partitions with
ICD's software without trashing the entire hard disk?

LONG: I just picked up a 85Meg hard drive from D&P (yay!). It
comes pre-formatted in equal 13.9 Meg partitions, and has about 8 Meg
of software already on it. I'd like to get a sub 5 Meg partition which
I can format as MFS (for Transverter). Is there a way I can split
the last partition into 10 & 4 Meg partitions without REPARTITIONING
THE ENTIRE HARD DRIVE and thereby toasting all the installed software?

Thanks MUCH in advance for suggestions to this e-mail address.

3147. **FREE** back issues of ST-Log

Newsgroup: comp.sys.atari.st.tech
Date: 1991-08-04 19:25:42 UTC
From: exuhag@exurchn1.ericsson.se
Message-ID: <1991Aug4.192542.16694@exurchn1.ericsson.se>
Source record: 47386
Cross-posted to: comp.sys.atari.st,comp.sys.atari.st.tech

I have just run across the following back issues of ST-Log in
my plethora of Atari stuff:

Issue 10, January 1987
Issue 11, February 1987
Issue 12, March 1987
Issue 14, May 1987
Issue 15, June 1987

These are all in good condtion and still have covers, etc--which is
not surprising since I never owned an ST (but I was planning on it back
then). I just can't bring myself to throw them out so I'm giving each
issue away for a 9x12 SASE (use an old issue or similar sized magazine
to figure the postage). Just let me know which issue(s) you are
interested in and I'll reserve it for you. If you want the whole lot I
can also work out a special deal.

If you like I could e-mail you Jim's RCP LHArced and uuencoded (it's 50K
after all that), I'd say it's worth it? I had it until I bought LaserC,
which includes a very complete RCP, once you're into GEM you might
consider it...

I'm interested, sounds useful to me.

On a similar note, has anyone heard of a program called WHATARC?
I've seen some discussion of it on Fidonet. From what I've seen it looks
like a program that you can config to handle any type of archive you have
a TTP for - but not a GEM menu type of thing like ARCSHELL or ARGSHELL.
If I understand it right, once you get it configured, you can just click
on a file and it processes it, no menu selections involved. There was
one guy who posted his configuration file and I noticed he had it
configured for ARJ and unARJ TTPs, I didn't even know ARJ was out for the
ST. I'd read in the info file of the IBM version that a full port was
planned, but didn't know ANY port had been done yet. Anyway....

3153. Color monitor gone bad

Newsgroup: comp.sys.atari.st.tech
Date: 1991-08-05 19:48:06 UTC
From: jgholm@crhc.uiuc.edu
Message-ID: <jgholm.681421686@lucky.crhc.uiuc.edu>
Source record: 47292

My SC1224 atari monitor just bit the dust.
For a while it would fail intermitently by flashing on
and off and sqeeking while it did this. It usually
warmed up and would stop flashing, but now it is dead.
It has no indication of life anymore.

I opened the box up and found that the board that noise was
coming from is the vertically mounted board on the right side
of the tube. I pulled this board and found that one of the
components had melted. The board markings say that the
component number is TH901. It looks like a capacitor (ceramic
type), but most of the other capacitors are marked
with C###, not TH###. Some of the other TH### parts have
coil symbols (inductor symbols) printed on the board, while
some of the inductors are labeled L###.

Unfortunately, this black component has NO markings on it.
I have no idea what to replace it with. I do not have
a schematic of the monitor, nor do I know where I can get one.
If anyone has any idea what this component is and what its
specs are, please post a response or send mail to me.
Information on where I can obtain a suitable replacement would
also be usefull.

Thanks in advance,
John

And Sometimes I wonder about Un*x and my news software!

To give a digest of what was lost...

Word Up looks for the string "PATH=" in system ram. When I
set up an environment variable in NeoDesk 3.02, Word Up (last version)
found that instead and thought its files were on ".;". To work
around, set the first path for the environment variable to be Word
Up's home directory.
When debugging a NeoDesk problem, do not just disable all auto
programs and desk accessories, but also all the NeoDesk .inf, .not,
and .mac files. You may also have to run NeoDesk from the desktop and
you may have to turn off the fast-load bit on the program under test
(if you have Tos >= 1.4).
BTW, what is the correct way to find a program's directory?
This was discussed on c.s.a.st.tech a while ago, I forgot the outcome.
Word Up now has this bug, a bug that leaves the mouse hidden
if you type control E, has ugly fonts, and is really ***SLOW***.
Only the PC ported dictionary and thesaurus are really good. Hope
Atari fixes it up right and rereleases it before A.D.2000 8-).

From: bjoern@drdhh.hanse.de
Message-ID: <3999.08.91@drdhh.hanse.de>
Source record: 47331

rwmcm@ccwf.cc.utexas.edu (Rob McMullen) writes:
>Can anyone give me information on the format of the relocation information
>that is located at the end of a program file? The basic structure is to
>use a byte offset to locate the next label that needs relocating. But,
>my question is: what happens if the offset is greater than 256 bytes
>away?

RelocTab starts with one long indicating first relocatable longword.
If any distance (indicated by the following bytes) is > 255, a distance
of 1 is used (unlikely to be needed / misalignment on 68030 'd be stupid),
which leads to 254 ! being added.
ReleocTable is terminated by 0.

hope that helps, Bjoern

Hi there!

I need some harddisk help:

I want to change my built-in Seagate ST157N-1 and to replace it
with my new Maxtor LXT 213 SY. My machine is an Atari TT030/6
with TOS 3.01, diskdriver AHDI 4.0.

I got only one data sheet with the disk, it says (in german):

Jumpersetting:
...
Jumper 5 (PIN 9,10) activates the Parity (cannot be switched off)
Jumper 4 (PIN 7,8) chooses the spin power option

Questions:
1. I know that the ICD Host Adaptor (often used to connect the
ST 157N-1 with a Mega ST) is not able to drive a SCSI disk without
paritity. This is an information from ICD Germany.

Will the host adaptor in the TT (bought 11/91) be able to drive
my new 210 MB disk?

2. What does Jumper 4 mean???

Thank for your replies, i won't install the new disk before!

BTW: Does somebody know how to connect the ST157N-1 with my Megafile 44?
I want to install it in the same case, are there any built in frames to
hold the disk?

Thanks Bernhard

Guys, I don't think Bob keeps posting this. I would guess a mailer/news
posting problem. So lets not take it out on Bob, OK? Talk to your news
manager and see if you can figure out how to kill it (like sending out
cancelation notices? or maybe something else.)

Look at the message. It has two paths, I think that Bob's message somehow got slapped on top of, but not completely covering someone elses message. Also check your message ID's for the various message of subject <None>, they are all different. So you might want to place something in your kill files to temporarily wipe these suckers out. Then once they've been expired from the net, we can remove those from our kill files. What to put in the kill file, I don't know, any suggestions? Or any other ideas about getting rid of these messages?

Kurt Olsen
kurto@cc.usu.edu

PS - Bob, I'm not trying to get you "black-listed" (ie. stuck in everyones kill files), but these do need to be taken care of, somehow.

>ST. I'd read in the info file of the IBM version that a full port was
>planned, but didn't know ANY port had been done yet. Anyway....
The sources of an arj lister/extractor are included in the package for PCs.
It works fine after some minor adaptions.

3183. Re: Why not a universal extractor?

Newsgroup: comp.sys.atari.st.tech
Date: 1991-08-06 20:44:48 UTC
From: ue@nathan.ruhr.de
Message-ID: <A0b9r8eo@nathan.ruhr.de>
Source record: 47198

In <Jgy861w164w@fquest.fidonet.org>, Mark Spacek writes:
[ARCLZH, calling extractors for different archives]

> I'm interested, sounds useful to me.
There are just two small problems stopping me from posting: I'm gonna use LHA2.01 for compressing and it will create -lh5- archives. I'm not gonna waste my time by installing a zoo version creating incorrect file dates because I did not set an environment variable (and noone knows the correct name and value for the US - what about Germany?)
And I'm not gonna waste my money by using the ineffective old lharc, zoo and arc methods creating huge archives. No Sir, definitely not.
You could say, hey, the new LHarc is not aviable for unix. I think that doesn't matter, after all, it's comp.binaries.ATARI.ST, not unix.
If it's not posted because it was packed with LHA2.01, then it's bad luck for you....

The second problem is the documentation. The program was written by a German and the documentation is - right, in German. Sorry, I'll have to do a translation first, it can take a week or two...

> On a similar note, has anyone heard of a program called WHATARC?
>I've seen some discussion of it on Fidonet. From what I've seen it looks
>like a program that you can config to handle any type of archive you have
>a TTP for - but not a GEM menu type of thing like ARCSHELL or ARGSHELL.
Yes, I know WHATARC, I'm in Fido, too. The disadvantage of whatarc is that it needs five parameters:
1. the action to be done (add or extract)
2. the path to the archive
3. the name of the archive
4. the path for the extracted files
5. the name(s) of the files to be extracted.

After all, it's a lot of typing. You can't use it as a standard application, TOS won't give it the correct path. Whatarc is a program written to work as an interface between the fido exporter and the packers, or in other words, between two programms. ARCLZH was designed as an interface between a human being and the packers.

>If I understand it right, once you get it configured, you can just click
>on a file and it processes it, no menu selections involved. There was
Nope. If you have configured it right, it will help the fido exporter to create the right packets at the right place using the right archiver. It was not designed as any kind of user interface.

>one guy who posted his configuration file and I noticed he had it
>configured for ARJ and unARJ TTPs, I didn't even know ARJ was out for the

>ST. I'd read in the info file of the IBM version that a full port was

There is an UNARJ for the st, I've never seen an ARJ. If you can get your
hands on one, please leave me a note.

3189. Warning: Two versions of Zoo 2.1

Newsgroup: comp.sys.atari.st.tech
Date: 1991-08-07 12:49:50 UTC
From: ralph@laas.fr
Message-ID: <RALPH.91Aug7144950@orion.laas.fr>
Source record: 47327
Cross-posted to: comp.sys.atari.st.tech,comp.sys.atari.st

There seem to be two versions of zoo 2.1 available for the Atari ST.
Before zoo21bin.zoo came available from the binaries newsgroup, I
recovered from atari.archive the following:

-rw-rw-r-- 1 1401 327325 Jul 14 23:14 zooV21.zoo

This latter version seems to have trouble with the recent postings:
lynxlib2.zoo and sokobin2.zoo.

Any comments?

Right you are, Ken!

In fact, he's already got it in there and he has also put in the new
LHARC stuff (compatible with Thomas Questor's version).

I don't know much about that sorta stuff, but Paul tells me they are
basically the same compression technique!

Imagine that.

Off it goes to the beta testers...

here we go again. now zoo is going to be ruined like lharc was. i suggest
that all those people who care to dabble with zoo 2.1 (and intend to post
it) get together and organize. there should be one version, not 10.

since there was a quasi-official version posted by our esteemed moderator,
i suggest at least initially, that we limit ourselves to that version
ALONE for posting zoo'd archives of any form (well, 2.01 is ok, too). i
hate to speak for steve, but it would not be a bad idea to either post
here your intentions for working on zoo or drop steve a line and let him
summarize who is doing what. if i had the time, i'd volunteer to coordinate
the zoo effort, but i don't. besides i'd rather work on more interesting
applications (like nroff 2.0 which i just started). i can live with slow/
big archives, as long as i can unpack them :-(

and it would not be a bad idea to contact rahul dhesi as well once we have
a working, optimized version and let him #ifdef atarist into the official
distribution.

if you do work on zoo, do NOT change the algorithm and do NOT change the
file format. optimize the heck out of it and even improve the interface
but do NOT do anything which would render archives unarchivable by the
"standard" release.

> since sozobon doesn't support such funtions as v_openvwk, graf_handle, and
> appl_exit, is there anywhere I can get a library of gem functions compatible
> with it.

Sure. That's what GEMFAST is for. GEMFAST 1.5 binaries and sources are
at atari.archive.umich.edu. Just include the appropriate libraries on
the command line when you run the compiler, i.e.:

cc -o program.prg program.c aesfast vdifast

GEMFAST 1.6 is included with a new ``Heat and Serve'' self-installing
Sozobon C package from Ian Lepore. I've been testing Ian's package for
a few weeks. It includes some bugfixes in GEMFAST, but the most significant
changes involve the ability to run Sozobon from the GEM Desktop or another
graphical shell. I'm running the new Sozobon C 1.30i directly from Gemini
by double-clicking on makefiles, and it works like a charm.

I'm going to ask Mike Dorman to upload it to a.a., since he's at an
Internet site and I'm stuck with UUCP and a 1200bps modem. (Really!)

Here is a summary of the changes I've noticed from the last official
release:

* A very polished GEM-based installation program creates the appropriate
directories and installs all the programs, header files, documentation,
etc., on your system.

* A GEM environment setter program is included so that global information
can be made available to the compiler components (and other programs, for
that matter) without requiring the use of a command shell.

* CC, the compiler driver program, supports a number of added switches:
-v[1][2][3][4] Numbers now cause cc to pass the -v flag to components.
-r <file> specifies an alternate runtime startup module.
-h holds the screen with a Hit any key... prompt before exit.

* HCC supports ANSI-style concatenation of adjacent string literals, and
there is no limit to the total length of a string assembled by the
concatenations. (ANSI-style concatenation means that if two strings are
separated only by white space, they are logically joined together as if
they were a single string literal.)

* HCC allows C++ comments (// delimits a comment).

* HCC fully supports void* pointers as a generic pointer type that does not generate a type mismatch warning. (This is especially welcome for the ob_spec field of an OBJECT.)

* Include files may be nested to any depth (former limit was 8).

* JAS, the assembler, no longer accepts C-style comments and comments set off by asterisks. (Stars in column 1 still delimit a comment, but semicolons are required to add comments to the end of a line of asm code.)

* JAS processes full ANSI escape sequences within string constants.

* JAS runs 50-100% faster than the original Sozobon version, by Ian's account.

* TOP, the optimizer, is more powerful. Ian has added several dozen new peephole sequences the he says shorten code sequences commonly found in GEM programming, such as access to an element in an array of structures via pointer and index into the array.

* The BUFSIZE environment variable can instruct HCC, TOP and JAS to use large i/o buffers for faster compilation if you have enough memory.

* MAKE is replaced by an enhanced version of a public-domain 'make' utility that is much more powerful. It works with a MAKE.INI file that you can tailor to your environment.

* DLIBS has been modified with several fixed routines, including the XARGS support routines, lmemcpy and bzero functions, and Ian's hand-coded assembler string library functions. (The bugfixes appear to be the same ones that are included in most commonly circulated versions of dlibs. I don't think the argument parser has been upgraded to support the ARGV standard.)

* DSTART.O is supplemented by alternate startup files (apstart.o and minstart.o) for creating GEM applications and desk accessories.

* GEMFAST 1.6 bindings for GEM functions are included.

* Some rarely encountered bugs are documented in detail.

It does this on TOS 1.4, too. Sure seems like a bug to me. The only
instance where this is really a problem is when you want to give the
file selector a pathname relative to the current working directory.
Calling fsel_input with ".\\" causes the same problems you describe
since it's a relative pathname. To solve this, I wrote a wrapper for
the file selector that expands an initial . in a pathname to the
complete specification for the current working directory. I.e.,
".*.c" -> "d:\usr\src*.c".

The wrapper also puts up a text string prompt. I've included the
C source below. Use it in good health!

Dave Baggett
dmb@wam.umd.edu

```
--------------------------------------------------------------------------------
/*
* Handy File Selector Wrapper
* by Dave Baggett
*
* This routine prompts the user for a filename using the GEM file selector
* and returns a pointer to a complete path specification for the file.
*
* ".\" is expanded to the full pathname of the current working directory
* to work around the GEM file selctor's problems with relative pathnames.
*
* The wrapper puts up a text message in the upper left corner telling the
* user what he/she/it is selecting. The screen is cleared before and after
* file selection.
*
* Remember to write the \'s as \\ in C; e.g., ".\\*.c"
```

```
*
* Example call:
*
* static char path[255] = ".\\*.c", file[14] = "file.c";
* static char filename[255];
*
* filename = file_select(path, file, "SELECT C SOURCE FILE");
* if (filename)
* load_c(filename);
*
* After the call, _filename_ will contain the complete path, e.g.,
* "d:\src\bin\foo.c".
*
* NOTE that the path and file parameters must be static strings (NOT
* literals) because the file_select routine modfies them. This is so that
* the path and file specification will be the same as the user set them
* (with the file selector) in the previous call. A call like
*
* file_select("d:\\foo\\*.c", "myfile", "PICK A FILE");
*
* will NOT work correctly because the path and file parameters are literals.
*
* This source code is in the public domain.

> [...]
```

Wouldn't ya know it? A bug in my comments. Get rid of

```
* static char filename[255];
```

and replace it with

```
* char *filename;
```

and it makes sense.

Sorry, folks.

This is a good thing to do, and thanks for the code. I've had problems
with some commercial applications (including PageStream) used across
multiple hard drive partitions because the application didn't pass a
full and proper path mask to the fsel.

> the TT is handling the TRAP exception.
>

The main difference is the format of the stack frame, it is different for
different processors.

voor the TRAP instruction they are as follows

```
68000: Status registers 68010: Status register 0
-------------- --------------
Program counter (high word) Program counter (high word) 2
-------------- --------------
Program counter (low word) Program counter (low word) 4
-------------- --------------
0010 | vector offset 6
--------------

68020
68030: Status registers 0
--------------
Program counter (high word) 2
--------------
Program counter (low word) 4
--------------
0010 | vector offset 6
--------------
instruction address (high word) 8
--------------
instruction address (low word) 10
--------------
```

note that on the 68000 the vector number can be found in the high byte of the
PC. Knowledge of the vector number can be used to have all exceptions point to
the same code but is not really needed with the TRAP instruction.
Which processor is in the computer can be checked with the following code

```
-------------
/* routine that checks configuration of the system
* recognizes: 68000/10/20/30, 68881/2, presence of MMU
*
* return codes: $0000 0000 CPU is 68000
* $0000 0001 CPU is 68010
* $0000 0002 CPU is 68020
```

```
* $0000 0003 CPU is 68030
* $0000 0100 FPU is 68881
* $0000 0200 FPU is 68882
* $0001 0000 MMU present
*
* or combinations
* example: 68030 with 68882 gives $0001 0203
*
* Assembled with TurboC MAS release 19
* Instructions for 68851 translated by hand and put in the program
* as initialized data because of bad translation by TurboC assembler
*
* from: "68030 assembly language reference", 1989
* by: Steve Williams
* publisher: Addison-Wesley Publishing Company, Inc.
* ISBN: 0-201-08876-2
*
* NOTE: these routines are not TOS specific, should run on any Motorola 68K
* CPU, TOS specific part is in C-function get_cpu
* No precaution are taken to insure that the changing of vectors can not
* be disturbed by interupts.
